## PingAccess Release Notes

---

### Release Notes

PingAccess is a centralized point of security and access control for Web applications and APIs, serving applications and other resources to clients outside an organization while still protecting internal interfaces from unauthorized access. PingAccess protects applications and APIs, enabling access control and identity-based auditing on incoming requests. Featuring a lightweight, highly scalable architecture, PingAccess complements PingFederate with centralized session management and URL-level authorization.

These release notes summarize the changes in current and previous product updates.

#### **PingAccess 5.3 - August 2019**

These enhancements and issue fixes are included in PingAccess 5.3, released in August 2019.

#### **Enhancements**

##### **Performance improvements**

Processing and response speed has been improved for Administrative API calls, engine node and replica administrative node replication, configuration imports, and configuration exports.

##### **Assign a trusted certificate group to a port**

You can now assign a trusted certificate group to a specific port. This lets you require client certificate authentication for all connections made to a specific engine listener. See [Defining an engine listener](#) for more information.

##### **Improved run.sh script compatibility**

The `run.sh` script has been enhanced to work with environments such as Alpine Linux and busybox.

##### **Addon SDK enhancement for third-party services**

The Addon SDK now lets a plugin declare that it needs a third-party service handle for an endpoint in the OIDC metadata. See [the OIDC Provider Javadoc](#) for more information.

##### **UI enhancement for resource creation**

When you view resources, a list of global unprotected resources is displayed, making it easier to avoid conflicts.

##### **Admin API audit logging improvement**

The audit logs for the Admin APIs now include response times.

##### **Startup logging improvement**

When PingAccess is started from the command line, the `pingaccess.log` file now includes the startup time.

##### **Upgrade utility logging improvement**

The upgrade utility now correctly displays warnings from the APIs.

### Configure PingFederate as token provider using metadata

You can configure PingFederate as a token provider using information from the OIDC metadata, meaning that much less information must be entered manually. See [Configuring PingFederate runtime](#) on page 242 for more information.

### View and refresh OIDC metadata

You can view and refresh the metadata for a configured token provider. See [Configuring PingFederate runtime](#) on page 242, [Configuring PingOne](#) on page 247, and [Configuring OpenID Connect](#) on page 247 for more information.

### JWT identity mapping exclusion lists

You can now configure a JWT identity mapping to exclude the attributes you specify and include all others. See [Creating a JWT identity mapping](#) on page 211 for more information.

### Added support for Coretto 8 and 11

Coretto 8 and Coretto 11 are now supported Java runtime environments.

### View token provider OIDC metadata in PingAccess

This feature allows administrators to view OIDC metadata that is available from the configured token provider.

### Import PingAccess license using Admin API

Import a PingAccess license via a **PUT** method on the `/license` endpoint.

### Web Session Scope rule

A new rule that examines the contents of the OpenID provider validation response and determines whether to grant access to a back-end target Site based on a match found between the scopes of the validation response and scope specified in the Web Session Scope Rule.

### Auditing for Unknown Resources and Redirects

The PingAccess UI and Admin API now support enabling or disabling auditing for redirects and unknown resources. This function was previously managed by the `pa.auditing.unknown.resource` property formerly available in `run.properties`.

### Log HTTP request and response headers for clients and applications

Easily modify audit log configuration to include details for HTTP request and response headers for clients and application.

### Resolved issues

Ticket ID	Description
N/A	Fixed potential security issues.
N/A	Fixed multiple upgrade utility performance issues.
CC-1004	Updated some clustering terminology for clarity. The optional subclustering feature has been renamed to runtime state clustering.
PA-11140	Fixed an issue causing the replica administrative node to replicate incorrect key data after being promoted to administrative node.

Ticket ID	Description
PA-11076	Clarified the error messages displayed when an application configuration does not load correctly.
PA-10240	Reduced the amount of time taken by a PingAccess database backup. Users encountering a slow login process can disable automatic backups by editing the <code>pa.backup.filesToKeep</code> parameter as described in the <a href="#">Configuration file reference guide</a> .
PA-11154	Fixed an issue that caused an incorrect Key Pair to be selected for TLS connections to virtual hosts in some cases.
PA-10239	Fixed an issue causing the Admin UI to time out during large configuration imports.
PA-10314	Fixed an issue causing large configuration imports to fail.
PA-10234	Fixed an issue causing large configuration imports to repeatedly restart.
PA-11165	Fixed an issue that caused the heartbeat API endpoint to ignore changes to the reserved application context root.
PA-10925	Fixed an issue that caused the pingfederate API endpoint to ignore hostname properties.
PA-10901	Fixed an issue that prevented old PingFederate metadata from being logged during a metadata update.
PA-10313	Fixed an issue causing excessive database growth on engine nodes.
PA-10829	Removed a Ping copyright statement from the <code>run.properties</code> file.
PA-10824	Fixed an issue that made the agent heartbeat endpoint unavailable after a key roll.
PA-10810	Fixed an issue causing invalid OAuth metadata attributes such as <code>client_id</code> to be suggested for attribute rules.
PA-10574	Fixed an issue where the Replica Console Heartbeat endpoint was not responding properly to requests.
PA-10798	Fixed an issue where a web session created in the PingAccess UI may not save correctly if a Client Secret was provided and the login type was specified as <code>POST</code> .

## Known issues and limitations

### Known issues

- As of the release of PingAccess 5.3, the current version of Safari and iOS 12 incorrectly treats cookies with a `SameSite` attribute of `None` as though it was set to `Strict`. This can break login flows for web sessions that do not set the `SameSite` attribute to `Disabled`, if PingAccess and the OIDC provider are on different domains.  
  
Chrome has proposed a change that would treat `SameSite` as `Lax` if it is not set. If this change is implemented, login flows for web sessions that set the `SameSite` attribute to `Disabled` can break. We recommend that you regularly evaluate the latest version of Safari and iOS 12, and update your `SameSite` setting to `Lax` or

None once Safari/iOS 12 correctly interprets a SameSite attribute of None.

- Use of TLSv1.0 has been maintained for use by legacy versions of Internet Explorer. Since continued use of TLSv1.0 is not recommended for security reasons, users should upgrade to the latest version of Internet Explorer to make use of the more secure TLSv1.1 or TLSv1.2.
- Engines and admin replicas do not connect to admin console if a combination of IP addresses and DNS names are used.
- The token processor can't connect to a JWKS endpoint via SSL when an IP is used rather than a hostname. To workaround this issue, add the hostname as the subject alt name on the key pair.
- When using Internet Explorer 11, you may not be able to view the full application or resource policy because the scroll bar is missing.
- Log files may contain excessive warnings issued by Hibernate during startup.

## Known limitations

- Internet Explorer and Firefox do not correctly support the HTML5 time tag. When using the Time Range rule, enter time in 24-hour format.
- When installing PingAccess as a Windows service using Windows PowerShell and Java 8, the error message "Could not find or load main class" can be safely ignored.
- Request Preservation is not supported with Safari Private Browsing.
- When using IE 11 to access the PingAccess admin console remotely, a fully qualified domain name or IP address must be specified. For example, `https://console.site.com:9000` and `https://172.17.8.252:9000` will work, while specifying only the host name, `https://console:9000`, will not.
- Incorrect handling for IPv6 literals in Host header. Note that IPv6 is not currently supported.

## Release notes archive

To access previous release notes, select the applicable version from the table of contents.

### PingAccess 5.2.3 - May 2019

PingAccess 5.2.3 is a cumulative maintenance release for PingAccess 5.2, which introduced several new features, including a customizable reserved application path, support for decrypting ID tokens, and support for PingOne for Customers as the token provider, along with several other enhancements. For more information, see the [release notes for PingAccess 5.2](#).

**Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
PA-10838	Fixed an issue causing ERROR-level log messages for failed TLS handshakes. Failed TLS handshakes are now logged at the DEBUG level.
PA-11015	Fixed an upgrade utility issue that prevented upgrades in some environments due to Groovy rule parsing errors.
PA-10954	Fixed an issue causing a 500 error code when using PingOne for Customers as a token provider when Admin API OAuth is being used.

**PingAccess 5.2.2 - April 2019**

PingAccess 5.2.2 is a cumulative maintenance release for PingAccess 5.2, which introduced several new features, including a customizable reserved application path, support for decrypting ID tokens, and support for PingOne for Customers as the token provider, along with several other enhancements. For more information, see the [release notes for PingAccess 5.2](#).

**Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
Multiple	Fixed potential security issues.
PA-10824	Fixed an issue that made the agent heartbeat endpoint unavailable after a key roll.
PA-10696	Fixed an issue that provided incorrect data in the detailed heartbeat endpoint response.
PA-10832	Fixed an issue that caused OIDC authentication responses to be delayed.
PA-10624 / PA-10667	Fixed an issue that caused recurring errors when non-standard HTTP or API methods were included in resources.
PA-10827	Fixed an issue that could cause a deadlock while refreshing PingFederate OIDC data, preventing configuration changes.
PA-10546	Fixed an issue causing POST preservation to be attempted for all unauthenticated requests to SPA support applications including API clients, resulting in incorrect status codes.
PA-10810	Fixed an issue causing invalid OAuth metadata attributes such as client_id to be suggested for attribute rules.

**PingAccess 5.2.1 - March 2019**

PingAccess 5.2.1 is a cumulative maintenance release for PingAccess 5.2, which introduced several new features, including a customizable reserved application path, support for decrypting ID tokens, and support for PingOne for Customers as the token provider, along with several other enhancements. For more information, see the [release notes for PingAccess 5.2](#).

**Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
Multiple	Fixed potential security issues.

## PingAccess 5.2 - December 2018

### Enhancements

#### Use PingOne for Customers as the token provider

PingAccess now includes native support for configuring **PingOne for Customers** as the OpenID Connect provider.

#### Support for Java 11

This release of PingAccess includes support for Oracle JDK 11 and Open JDK 11 in addition to support for Java 8. As of version 11, Server JRE is no longer available. Note that while other combinations may function as expected, the only tested and supported cluster configurations are those where each node utilizes the same JDK distribution.

#### Configure the reserved application path

You can now use the PingAccess Admin API to configure the reserved application path (`/pa`). This feature is useful for customers who need to protect application resources that natively use the default PingAccess reserved application path.

#### Decrypt encrypted ID tokens

To reduce backchannel communication between PingAccess and the token provider, PingAccess is now able to decrypt ID tokens that have been encrypted by the token provider using a public key that the token provider obtains from PingAccess.

#### Local validation of JWT OAuth 2.0 Bearer Access Tokens

To reduce backchannel communication between PingAccess and the token provider, PingAccess can locally validate signed (JWS) and/or encrypted (JWE) access tokens for API calls.

#### Read and use PingFederate metadata

PingAccess reads metadata from PingFederate and uses the information to build authorization, token, and other endpoints.

#### API to retrieve resource path pattern evaluation order

An API endpoint is now available to retrieve application resource path pattern evaluation order.

#### Dynamically populate PingFederate token generator IDs

If PingFederate Administration is configured, PingAccess now populates available Token Generator IDs while configuring a Token Mediator Site Authenticator.

#### Groovy enhancements

Enhancements to Groovy script functionality have been included that allow you to get all values for any header field and to dump headers via Groovy script to aid with debugging.

### Resolved issues

Ticket ID	Description
N/A	Fixed potential security issues.
PA-10325	Fixed an issue where engine requests to sync configuration based on a configurable interval were timing out.

<b>Ticket ID</b>	<b>Description</b>
PA-10259	Fixed an issue where PingAccess was not properly encoding ampersand after post preservation.
PA-10335	Fixed an issue where evaluation of nested RuleSetGroups were failing for agent requests.
PA-10463	Fixed an issue where references to AuthnRequirement IDs were not being retained across an upgrade, resulting in an impact to Admin SSO functionality.
PA-10281	Fixed an issue that caused interoperability problems when using a Site Authenticator Token Mediator for a resource specified as being globally unprotected.
PA-10304	Fixed an issue where, in some cases, engine key data was not being migrated successfully for older versions of PingAccess.

### **PingAccess 5.1.3 - March 2019**

PingAccess 5.1.3 is a cumulative maintenance release for PingAccess 5.1, which introduced several new features, including Custom OIDC Scopes, SPA Support, improved Redirect and Rejection handling, Unprotected Resources and Enhanced Path Matching patterns, along with several other enhancements. For more information, see the [release notes for PingAccess 5.1](#).

#### **Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
Multiple	Fixed potential security issues.
PA-10281	Fixed an issue where access to a globally unprotected resource would cause an error if a token mediator site authenticator was associated with the site.
PA-10305	Fixed a threading issue in caching implementation.
PA-10325	Fixed an issue where engine nodes stopped polling for configuration.
PA-10335	Fixed an issue where Rule Set Group evaluation was failing for agent requests.
PA-10463	Fixed an issue where Authentication Requirement IDs were not updated on upgrade.

### **PingAccess 5.1.2 - October 2018**

PingAccess 5.1.2 is a cumulative maintenance release for PingAccess 5.1, which introduced several new features, including Custom OIDC Scopes, SPA Support, improved Redirect and Rejection handling, Unprotected Resources and Enhanced Path Matching patterns, along with several other enhancements. For more information, see the [release notes for PingAccess 5.1](#).

#### **Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
PA-9874	Fixed an issue where a Web Session Attribute rule would fail if the attribute name was formatted as a URI.
PA-9983	Fixed an issue where PingAccess was converting site hostnames to IP addresses when being sent to a forward proxy in a CONNECT request.

PA-9990	Fixed an issue where an upgrade would fail if API applications were being migrated and an appropriate OAuth token provider was not configured.
PA-10021	Fixed an issue where errors were being generated and stack traces were being logged when policy evaluation succeeded.
PA-10035	Fixed an issue where path patterns were not allowing for trailing whitespace.
PA-10179	Fixed a potential security issue.

### PingAccess 5.1.1 - August 2018

PingAccess 5.1.1 is a cumulative maintenance release for PingAccess 5.1, which introduced several new features, including Custom OIDC Scopes, SPA Support, improved Redirect and Rejection handling, Unprotected Resources and Enhanced Path Matching patterns, along with several other enhancements. For more information, see the [release notes for PingAccess 5.1](#).

### Resolved issues

Ticket ID	Description
PA-9806	Fixed an issue where PingAccess did not honor enabled TLS protocol version(s) configuration when acting as a TLS server.
PA-9808	Fixed an issue where an invalid TLS cipher specified in run.properties would lead to connectivity issues.

### PingAccess 5.1 - June 2018

#### Enhancements

##### Custom OIDC scopes

Explicitly specify the scopes you want to obtain when requesting the ID token. If a token provider is configured, select published scopes from a list based on the client ID you specify. You can specify an unverified scope by entering the scope value in the field provided.

For more information, see [Create a Web Session](#) and [Configure Admin UI SSO Authentication](#).

##### Single Page Application (SPA) support

SPA support merges the conventional 401 unauthorized response of an API application with the traditional 302 redirect response of a web application when a client request does not contain an authentication token. The SPA supported result is a 401 response containing a JavaScript body that can initiate a 302 redirect.

SPA support is useful for protected applications that may receive requests in which the client type is unknown, and no token nor cookie is present. SPA support provides a combined response containing information that both web and API clients can act upon.

For more information, see [About SPA support](#).

##### Redirects

Globally redirect the `host:port` of specific incoming requests to that of a different target. This feature is useful in redirecting HTTP requests to an equivalent HTTPS URL.

For more information, see [Redirects](#).

##### Redirect rule

Use a redirect rule with an application to specify a fixed URL that a user agent should request in response to being denied access to the requested resource. Redirect rules can be applied to one or more applications.

For more information, see [Redirect rule](#).

### Rejection handlers

Define the action to take when a request to an application or resource is rejected by policy evaluation. This feature allows you to decide if you want to display an **error template** or **redirect** the user to another URL for error details, instructions, or additional actions. You can specify the response status code that you want to send if policy evaluation rejects access.

For more information, see [Manage rejection handlers](#).

### Rejection rule

Use a rejection rule with an application to specify the action to take when a request to an application or resource is rejected by policy evaluation. A rejection rule uses [Rejection handlers](#) to define which action you want to take, either rejecting the request and displaying an error template, or redirecting the user to another URL for error details, instructions, or additional actions.

For more information, see [Rejection rule](#).

### Server-side cipher ordering

Define the order for cipher suite usage to help ensure the most secure cipher suites are used first, regardless of the client request. On new installs, or in the case of an upgrade to release 5.1, this behavior is the default.

For more information, see [Cipher suite ordering for HTTPS listeners](#).

### Global unprotected resources

Specify resources to be unprotected at a global level for all applications. This feature allows you to indicate certain resources that have no authentication requirements. These entries must start with a slash (/) and may contain one or more wildcard characters (\*). Examples include:

- `/*.jpg`
- `/resources/*.css`
- `*/resources/favicon.ico`

Use Global unprotected resources when you want to allow unauthenticated access to a particular resource for all applications.

To configure a global unprotected resource, see [Manage global unprotected resources](#).

### Application unprotected resources

Specify resources to be unprotected at the application level. This feature allows you to indicate certain resources within an application that have no authentication requirements. Processing rules are applied to unprotected resources where applicable. No application or resource access control policy is applied.

Use Application unprotected resources when you want to allow unauthenticated access to a particular resource for a single application.

To configure an application unprotected resource, see [Manage application resources](#).

### Enhanced path-matching patterns

PingAccess now supports the use of regular expressions as path patterns for a resource. The supported syntax is that documented by the [RE2 wiki](#).

To use regular expressions as path matching patterns, you must enable **Resource Ordering**. For more information on using regular expressions, see [Manage application resources](#).

### Resource ordering

Manually specify the order in which path patterns are evaluated for an application. This allows more explicit control of the policies that are applied to a request for a resource. Resource ordering also enables the use of regex path patterns.

For more detailed information on resource ordering and using regex path patterns, see [Resource ordering](#).

### Third-party services

Create third-party services to define the destination for HTTPS outbound calls. Third-party services are used by custom plugins to indicate how the HTTP client will communicate with the destination. The configuration of a third-party service is similar to that of a site.

For more information on configuring third-party services, see [Manage third-party services](#).

For more information on creating custom plugins to use these third-party services, see [Integrating with third-party services](#).

### HTTPS Client SDK Support

Integrate custom plugins with external third-party services via HTTP. Example services may include those for authorization or auditing. For more information, see [Integrating with third-party services](#).

### In-Use Information for Key Pairs, Trusted Certificate Groups, and Third-Party Services

Easily see which plugins are using key pairs, trusted certificate groups, and third party services. To see where these components are being used, navigate to:

- **Main > Sites > Third-Party Services**. Expand the third-party service and click the **References** tab.
- **Settings > Security > Certificates**. Expand the trusted certificate group and click **Show References**.
- **Settings > Security > Key Pairs**. Expand the key pair and click the **References** tab.

### Removal of SHA1-based cipher suites

Usage of SHA1-based cipher suites has been deprecated in PingAccess 5.1. Legacy browsers may require the addition of SHA1-based ciphers to negotiate a cipher suite with the server. In this case, add the following ciphers to the `engine.ssl.ciphers` property in `run.properties` and restart PingAccess:

```
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
TLS_RSA_WITH_AES_128_CBC_SHA
```

### Resolved issues

Ticket ID	Description
PA-8754	Modified engine log error output to include rule and class name details when a configuration update fails due to a missing JAR.

### PingAccess 5.0.6 - March 2019

PingAccess 5.0.6 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

#### Resolved issues

Ticket ID	Description
Multiple	Fixed potential security issues.

### PingAccess 5.0.5 - August 2018

PingAccess 5.0.5 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

#### Resolved issues

Ticket ID	Description
PA-9806	Fixed an issue where PingAccess did not honor enabled TLS protocol version(s) configuration when acting as a TLS server.
PA-9876	Fixed an issue where engines would take an excessive amount of time to start due to unbounded database growth.

### PingAccess 5.0.4 - June 2018

PingAccess 5.0.4 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

#### Resolved issues

Ticket ID	Description
PA-9475	Fixed an issue where a change to the SDK disallowed the use of the <code>com.pingidentity.policy.error.info</code> Exchange property in Groovy scripts.
PA-9529	Fixed an issue where an exception occurred while parsing an access token that contains integers as attribute values.
PA-9632	Fixed an issue where, under certain conditions, policy rules were not being evaluated as expected.

### PingAccess 5.0.3 - March 2018

PingAccess 5.0.3 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

#### Resolved issues

Ticket ID	Description
PA-9318	Fixed an issue where an incorrect database password could corrupt the database.
PA-9335	Fixed an issue when upgrading from release 4.3.x or lower, where the upgrade may have failed due to a Java comparison method contract violation, as indicated in the upgrade log.
PA-9350 PA-9356	Fixed an issue where the <b>Narrow By</b> filtering functions for rules, rule sets, and rule set groups were not functioning properly.
PA-9359	Fixed an issue where the user interface may not function correctly after an application has been deleted.

### PingAccess 5.0.2 - March 2018

PingAccess 5.0.2 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

### Resolved issues

Ticket ID	Description
PA-9200	Fixed an issue where a retry triggered by the availability profile HTTP status codes configuration used the target IP address rather than the IP of a configured proxy.
PA-9201	Fixed an issue where, under some conditions, the read timeout was not being enforced for an availability profile.

### PingAccess 5.0.1 - December 2017

PingAccess 5.0.1 is a cumulative maintenance release for PingAccess 5.0, which introduced several new features, including Ping Identity Cloud Automation Repo, Zero downtime upgrades, a new application type (Web +API), along with several other enhancements. For more information, see the [release notes for PingAccess 5.0](#).

**Important:** For customers upgrading to the 5.0 release from an earlier version, please note that there are potentially breaking changes to plugins and Groovy scripts. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

Likewise, the Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

### Resolved issues

Ticket ID	Description
PA-8706	Fixed a performance issue that is encountered when you create and assign a large number of virtual hosts to an application.
PA-7936	Fixed an issue in the Upgrade Utility.

### PingAccess 5.0 - December 2017

#### Enhancements

##### PingIdentity Cloud Automation Repo

An automated cloud deployment of PingAccess for Amazon Web Services. This solution, both for customers with and without existing AWS resources, allows administrators to easily configure a functioning environment using PingAccess and an optional basic PingFederate deployment. The templates included with the package will guide you through the setup of all necessary components, including the S3 bucket, EC2 instances, routing and security parameters, and naming conventions.

For more information on deploying this solution, see the [PingAccess for AWS: Solution setup guide](#).

**Note:** The PingAccess for AWS solution does not yet support agent deployments. For more information, see [Known limitations](#) on page 11.

##### Zero downtime upgrades

Upgrade a cluster to PingAccess 5.0 with no downtime. This updated procedure takes advantage of new functionality that ensures availability during the entire upgrade process without impacting existing user sessions.

To learn about the updated Zero Downtime Upgrade process, see [PingAccess: Zero Downtime Upgrade](#).

##### Web + API applications

PingAccess now supports the concept of a heterogeneous application that allows configuration of both Web and API settings. The PingAccess runtime inspects the inbound request for the presence of a web session cookie or an OAuth token and applies the access control policy defined for the type of authentication token in the request. Administrators can specify a default fallback type for application requests that do not include a web session cookie or OAuth token.

##### Security enhancements for exported configuration data

By default, all sensitive configuration data exported from PingAccess is now encrypted with the system master key (the "host key"), helping to ensure confidentiality of data at rest. Additionally, when a `MasterKeyEncryptor` plugin is configured, the host key will be encrypted and included in the exported data in order to support export/import of configuration data across clusters with different host keys. Administrators still have the

less secure option of including a generated encryption key in the exported data. This feature can be configured using the `admin.export.encryption.mode` property in `run.properties`.

Configurable values for this property are:

- **MASTER\_KEY** - The host key is encrypted and included in exported data. This option requires that you have a master key encryptor configured to encrypt and decrypt the necessary data. Customers using this option must supply and configure the master key encryptor.
- **PORTABLE\_INSECURE** - The encrypted host key is included in exported data. In this case, the host key should be manually removed from data and stored safely to prevent unauthorized usage of the host key.

### Java Addon SDK modifications

Plugins built against the Java Addon SDK for PingAccess 5.0 are now required to be built with JDK 8, as the SDK for PingAccess 5.0 uses Java 8 features. Previously, plugins could be built with either JDK 7 or JDK 8.

**Important:** There are potentially breaking changes with this release. Plugins built with JDK 7 may not function as expected and should be reviewed for migration to JDK 8. For more information, see the [PingAccess Addon SDK for Java Migration Guide](#).

### Groovy API enhancements

The Groovy API is enhanced for the addition of some objects. Groovy scripts should be reviewed for necessary changes. For more information on these changes, see the [Groovy Development Reference Guide](#).

#### Note:

Previous functionality that allowed Groovy scripts to leverage an undocumented capability to use the Addon SDK APIs has been removed. Methods and types added to the Groovy API align with the previous version of the Addon SDK. As a result, if existing Groovy scripts leverage Addon SDK APIs that are not available in the new Groovy API, they will need to be ported to only use the methods and types available in the new Groovy API before upgrading to PingAccess 5.0.

### Enhanced engine and replica admin trusted certificate functionality

This release introduces enhanced engine and replica admin trusted certificate functionality that allows an administrator to choose the Trusted Certificate that gets exported for an engine or replica admin in the configuration zip file.

### Administrative API version 3

PingAccess Admin REST APIs have been updated to version 3 with several changes, including the addition and removal of some fields that may warrant a migration of existing code. For more information about these changes and information on how to migrate existing code, see [Administrative API updates](#) on page 23.

### Improved upgrade support for custom plugins

This feature adds a new `-i` command-line option to the PingAccess Upgrade Utility, as well as support by installers, that allows an administrator to specify a directory containing custom plugins compiled against the new SDK.

If you have custom plugins and wish to perform an upgrade, you will need to rebuild the plugins against the new Java SDK, then run the Upgrade Utility manually with the new `-i` command-line option to include their directory.

## Resolved issues

Ticket ID	Description
PA-6272	Fixed an issue where the installers did not validate administrator credentials before continuing.
PA-6975	Fixed an issue where, during active sessions, PingAccess did not enforce the presence of an access token in the PingAccess cookie when a web session configuration was modified to require the access token.
PA-7618	Fixed an issue where the Windows installer failed to install PingAccess as a service during an upgrade.
PA-7629	Fixed an issue where, during an upgrade, the Linux installer showed a status of FAILED if you chose not to replace the existing service.
PA-7931	Fixed an issue where PingAccess X-Forwarded-For IP address validation was not allowing port numbers.
PA-7958	Fixed an issue where a race condition would cause the engine to miss the auth token key roll.
PA-7971	Fixed an issue where, during an upgrade on RHEL 7 using the Linux installer, the install may show as FAILED due to an error starting the systemd PingAccess service.
PA-7975	Fixed an issue where Auth token management settings were not being properly migrated during an upgrade.
PA-8056	Fixed an issue where a race condition would cause the engine to miss configuration updates.
PA-8250	Fixed an issue where PingAccess was failing on a call to retrieve a token from the token provider.
PA-8380	Fixed a potential security issue.
PA-8382	Fixed an issue where the upgrade would fail if a third party token provider was enabled but not configured.
PA-8477	Fixed an issue where a disabled Site send token would cause the replaced Authorization header field to be removed.

### *Administrative API updates*

With PingAccess 5.0, the administrative API interface is updated to version 3. This update includes changes to some API endpoints.

Administrators who have written code that uses the API endpoints to automate administrative tasks will need to update their code to use the new endpoints.

**Note:** The fundamental change in all administrative API calls will be a change in the endpoint URI from `/pa-admin-api/v2` to `/pa-admin-api/v3`. For example, if you made a call to `/pa-admin-api/v2/pingfederate/admin`, your code would need to be updated to point to `/pa-admin-api/v3/pingfederate/admin`

The following table identifies specific API changes that may need more updates than just the path to the API endpoint.

Endpoint	Change Description
/applications	<p>This endpoint will now prevent creation of protected Applications if the corresponding token provider configuration is not set. For a protected Web Application, the PingFederate Runtime or the OpenID Connect provider must be configured to be able to create or update a protected Web Application via the /applications endpoint. For a protected API Application, the PingFederate OAuth Resource Server or OAuth Authorization Server must be configured to be able to create or update a protected API Application via the /applications endpoint. The token provider configuration can still be cleared via the appropriate DELETE endpoints if protected Applications are configured but disabled. However, doing so will prevent future updates to existing protected Applications until the corresponding token provider configuration is set.</p> <p>The <code>applicationType</code> field has been updated to add support for Dynamic (Web + API) applications. Additionally, the <code>defaultAuthType</code> and <code>identityMappingIds</code> fields have been added in support of Web + API applications.</p> <p>The format of the <code>policy</code> field has been updated to include the application type. For example:</p> <pre data-bbox="867 1066 1458 1436">{   ...   "policy": {     "Web": [       {         "type": "Rule",         "id": 20       }     ],     "API": []   }   ... }</pre>

Endpoint	Change Description
/applications/{id}/resources	<p>This endpoint has been updated to include the <code>defaultAuthTypeOverride</code> field in support of Web + API application types. Use this field to override the default of an application for a resource. A value of <code>null</code> indicates no override.</p> <p>The format of the <code>policy</code> field has been updated to include the application type. For example:</p> <pre data-bbox="867 464 1463 863"> {   ...   "policy": {     "Web": [       {         "type": "Rule",         "id": 20       }     ],     "API": []   }   ... }</pre>
/adminConfig/replicaAdmins/{id}/key/{keyId} and /engines/{id}/key/{keyId}	<p>The DELETE operation has been removed because the <code>keyId</code> field for public keys is no longer available.</p> <p>Public keys can be deleted by removing them from the <code>keys</code> field of a <code>ReplicaAdmin</code> or an <code>Engine</code> entity supplied to the <code>PUT /adminConfig/replicaAdmins/{id}</code> or <code>PUT /engines/{id}</code> operations, respectively.</p>
/adminConfig/replicaAdmins and /engines	<p>For all GET, PUT, and POST operations that return a <code>ReplicaAdmin</code> or an <code>Engine</code> entity, the <code>PublicKey</code> objects contained in the <code>keys</code> field no longer contain an <code>id</code> field.</p> <p>In addition, the <code>value</code> field of <code>PublicKey</code> has been renamed to <code>jwk</code> to better represent the fact that the data is a JSON Web Key. The field type has also been changed from a <code>string</code> to a <code>JSON object</code>.</p>
/ruleSets	<p>The <code>RuleSet</code> type field has been renamed to <code>elementType</code> to better reflect the fact that the type represents what sort of elements are contained in the <code>RuleSet</code>.</p>
/rulesets/types	<p>This endpoint has been renamed to <code>/rulesets/elementTypes</code> to better reflect the fact that the types represent what sort of elements can be included in a <code>RuleSet</code>.</p>

Endpoint	Change Description
/config/export	The configuration data returned by a GET operation no longer contains an <code>encryptionKey</code> field (by default). Instead, the system master encryption key is used to encrypt sensitive data. If a <code>MasterKeyEncryptor</code> plugin is configured, a new <code>masterKeys</code> field will be included, which contains the encrypted master key.
/webSessions	The <code>consultServerDurationInSeconds</code> field has been removed as it is no longer used by <code>PingAccess</code> . The length of time an Agent caches <code>WebSession</code> policy decisions is dependent on the lifetime of the sessions as determined by <code>idleTimeoutInMinutes</code> and <code>sessionTimeoutInMinutes</code> and the intervals defined by <code>refreshUserInfoClaimsInterval</code> and <code>pfsessionStateCacheInSeconds</code> .
/auth/oidc	The <code>clientId</code> and <code>clientSecret</code> fields have been removed. Instead, use the <code>clientCredentials</code> object contained in the object <code>oidcConfiguration</code> to set the <code>clientId</code> and <code>clientSecret</code> fields. Further, the <code>oidcConfiguration</code> field is now required. Previously, it was optional.
/identityMappings	The <code>identityMappingPairs</code> field has been removed. In <code>PingAccess 4.1</code> , <code>/identityMappings</code> was converted to support custom <code>IdentityMappings</code> and as a result, uses an extensible configuration model to support arbitrary configuration for custom <code>IdentityMappings</code> . With this change, the <code>IdentityMapping</code> from previous versions become the <code>HeaderIdentityMapping</code> . The schema for configuring a <code>HeaderIdentityMapping</code> can be retrieved from the <code>/identityMappings/descriptors/headeridentitymapping</code> endpoint. The data previously contained in a <code>identityMappingPair</code> will map to an element in the <code>attributeHeaderMappings</code> array. Specifically, the <code>IdentityMappingPair.nameToExtractValueFrom</code> field will map to the <code>attributeName</code> field in an <code>attributeHeaderMapping</code> , the <code>IdentityMappingPair.nameToInjectValueInfo</code> field will map to the <code>headerName</code> field in an <code>attributeHeaderMapping</code> , and the <code>IdentityMappingPair.subject</code> field will map to the <code>subject</code> field in an <code>attributeHeaderMapping</code> .
/webSessionManagement	The <code>maxNumberOfKeys</code> field has been removed. Previously, this field is no longer exposed in the Admin API.

### PingAccess 4.3.6 - March 2019

PingAccess 4.3.6 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
Multiple	Fixed potential security issues.

### PingAccess 4.3.5 - August 2018

PingAccess 4.3.5 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
PA-9806	Fixed an issue where PingAccess did not honor enabled TLS protocol version(s) configuration when acting as a TLS server.
PA-9876	Fixed an issue where engines would take an excessive amount of time to start due to unbounded database growth.

### PingAccess 4.3.4 - December 2017

PingAccess 4.3.4 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
PA-8706	Fixed a performance issue that is encountered when you create and assign a large number of virtual hosts to an application.
PA-7936	Fixed an issue in the Upgrade Utility.

### PingAccess 4.3.3 - October 2017

PingAccess 4.3.3 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
PA-8380	Fixed a potential security issue.

### PingAccess 4.3.2 - September 2017

PingAccess 4.3.2 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
PA-7629	Fixed an issue where, during an upgrade, the Linux installer showed a status of FAILED if you chose not to replace the existing service.
PA-8205	Fixed a potential security issue.
PA-8248	Fixed an issue where dbuserpasswd and dbfilepasswd .sh and .bat files would fail.
PA-8253	Fixed an issue where a race condition would cause the engine or admin replica to miss an auth token key roll or a web session key roll
PA-8254	Fixed an issue where a race condition would cause the engine to miss configuration updates.
PA-8255	Fixed an issue where an engine data.zip could not be downloaded after a configuration import.

### PingAccess 4.3.1 - August 2017

PingAccess 4.3.1 is a cumulative maintenance release for PingAccess 4.3, which introduced several new features, including client certificate authentication, admin session revocation, support for PostgreSQL audit logging, and support for standards based OIDC single logout. For more information, see the [release notes for PingAccess 4.3](#).

#### Resolved issues

Ticket ID	Description
PA-7632	Fixed an issue where, during an upgrade on RHEL 7 using the Linux installer, the install may show as FAILED due to an error starting the systemd PingAccess service.
PA-7931	Fixed an issue where PingAccess X-Forwarded-For IP address validation was not allowing port numbers.
PA-7975	Fixed an issue where Auth token management settings were not being properly migrated during an upgrade.

### PingAccess 4.3 - June 2017

#### Enhancements

##### PingAccess for Azure AD

A version of the PingAccess license is available for premium users of Microsoft's Azure AD. This license permits the use of a limited feature set supporting integration with the Azure AD Application Proxy and provides secure access for up to 20 legacy on-premises applications. Users are able to take advantage of the full PingAccess feature set by purchasing a full license. To learn more, see:

- [PingAccess for Azure AD overview](#)

- [Getting started with PingAccess for Azure AD](#)

### Token provider specific attribute transformation

PingAccess provides a mechanism that transforms incompatible attribute payload data received from Azure AD's OIDC UserInfo endpoint and retrieves the display names for groups from the Azure AD Graph API.

### Client certificate authentication

PingAccess now facilitates client certificate authentication with protected applications that accept client certificates as HTTP headers. This feature works by retrieving client certificates sent by the browser during the SSL/TLS handshake with PingAccess and adding them, through the use of identity mappings, (JWT and Header), to the HTTP request headers sent to a site. An example scenario is using PingAccess to protect the public interfaces of PingFederate when user authentication requires a certificate to authenticate. For more information on PingFederate configuration, see [Defining Proxy Options](#).

### Administrator session revocation

PingAccess now supports full administrator SSO session revocation. When using PingFederate as the token provider, PingAccess can be configured to utilize admin SLO functionality that redirects PingAccess to the SLO endpoint to initiate the sign-out process. When using PingAccess basic authentication, server side session tracking is used to verify the session and deny access for invalidated cookies after sign-out.

### Support for systemd services

The Linux installer now supports installation of systemd services on RHEL 7, while maintaining System V service support on RHEL 6. The systemd init system offers more robust service management and a simpler configuration. When upgrading PingAccess on a system that supports systemd, you will be given the option to replace an existing System V service with a newer systemd service. A template service unit configuration file is also provided for manual installation of systemd services on non-RHEL systems.

### PingAccess support for PostgreSQL audit logging

In addition to existing audit logging options for Oracle and MS SQL Server databases, PingAccess now supports database audit logging for the API, engine, and agent to PostgreSQL databases. Configure PostgreSQL audit logging using the `/conf/log4j2.db.properties` and `/config/log4j2.xml` files available in the PingAccess installation directory.

### Support for standards based OIDC single logout

Support has been added for administrator single logout when using a compatible third party OpenID Connect provider. A compatible provider supports OpenID Connect Session Management 1.0.

### Improved configuration export and import

The format of the exported configuration data has been modified to more closely align with the PingAccess REST API and to provide a more user-friendly JSON structure. In addition, sensitive data is now obfuscated to help protect data at rest.

### PingAccess support on additional operating systems

PingAccess Server is now supported on the following systems:

- SUSE Linux Enterprise Server v12
- RedHat Enterprise Linux 7.3
- Windows Server 2016

## Resolved issues

Ticket ID	Description
Various	This release contains multiple UI improvements and enhancements.
PA-5208	Fixed an issue where reverse DNS lookup was failing on PingAccess startup.
PA-5683	Fixed an issue where authentication requirements rules were not processing in the correct order.
PA-6332	Fixed an issue where an OAuth scope and attribute policy would succeed on an unprotected application when <code>negate</code> is set to <code>true</code> .
PA-6396	Fixed an issue where logouts were not being handled correctly when using a third party token provider.
PA-6582	Fixed an issue where a warning was not issued when a rule that requires an identity was assigned to an unprotected application.
PA-6585	Fixed an issue where nonce cookies were not being removed after unsuccessful requests.
PA-6776	Fixed an issue where an admin was taken to the basic authentication page after their session expired if using admin SSO.
PA-6884	Fixed an issue where the policy screen did not allow scrolling when using Internet Explorer 11.
PA-6900	Fixed an issue where a value of 0 was not accepted as a valid Session Poll Interval.
PA-6965	Fixed an issue where the upgrade utility was failing when there are spaces in the path.
PA-6973	Fixed an issue where PingAccess was calculating the agent token cache TTL for a web session incorrectly which may have resulted in an agent not consulting the PingAccess policy server when either the PingFederate Session State Cache Interval or the Refresh User Attributes Interval as configured for the web session had elapsed.
PA-6981	Fixed an issue where sessions were not being invalidated after changing the Web Session Issuer.
PA-7033	Fixed an issue where no warning was displayed when modifying the Admin SSO configuration that may have resulted in unexpected lockout.
PA-7040	Fixed an issue where a JWT identity mapping attribute with a period in its name was not being mapped into a claim.
PA-7151, PA-7190	Fixed issues with the encoding of special characters used in searches.
PA-7350	Fixed an issue where a Client Certificate JWT claim name didn't support nested (dot notated) formatting.
PA-7603	Fixed an issue where the installer was hanging during upgrade because the service had not yet stopped.

### PingAccess 4.2.4 - March 2019

PingAccess 4.2.4 is a cumulative maintenance release for PingAccess 4.2, which introduced several new features, including improved admin UI workflow, certificate trust chains, event storage in MS SQL, agent policy server failover, unknown resource handling, forward proxy handling, and installer support for upgrades. For more information, see the [release notes for PingAccess 4.2](#).

### Resolved issues

Ticket ID	Description
Multiple	Fixed potential security issues.

### PingAccess 4.2.3 - April 2017

PingAccess 4.2.3 is a cumulative maintenance release for PingAccess 4.2, which introduced several new features, including improved admin UI workflow, certificate trust chains, event storage in MS SQL, agent policy server failover, unknown resource handling, forward proxy handling, and installer support for upgrades. For more information, see the [release notes for PingAccess 4.2](#).

#### Resolved issues

Ticket ID	Description
PA-6929	Fixed an issue where multiple nonce cookies were created during abandoned authentication attempts.
PA-6943	Fixed an issue where PingAccess was not encoding some data correctly when communicating with the token endpoint.
PA-6978	Fixed an issue where rate limiting rules were not correctly enforcing the application scoped rate limit.
PA-7035	Fixed an issue where identities were being associated with authentication requests to anonymous resources.
PA-7038	Fixed an issue where there was no redirect or success banner following successful object creation.
PA-7042	Fixed an issue where warnings were being included in logs when an HTTP response write error occurs.

### PingAccess 4.2.2 - February 2017

PingAccess 4.2.2 is a cumulative maintenance release for PingAccess 4.2, which introduced several new features, including improved admin UI workflow, certificate trust chains, event storage in MS SQL, agent policy server failover, unknown resource handling, forward proxy handling, and installer support for upgrades. For more information, see the [release notes for PingAccess 4.2](#).

#### Resolved issues

Ticket ID	Description
PA-6437	Fixed an issue where some velocity variables were not present in some conditions.
PA-6551	Fixed an issue where ID Token attributes were incorrectly included in the PingAccess cookie if <code>Include User Info in ID Token</code> was enabled and <code>Cache User Attributes</code> is enabled in the web session.
PA-6577	Fixed an issue in Basic Administrator Authentication where the "Password change failed" message was being displayed even when the password change succeeded.
PA-6602	Fixed an issue where some <i>Warning</i> messages were not being displayed on the Policies page.
PA-6695	Fixed an issue where PingAccess was using the incorrect proxy to communicate with PingFederate.

Ticket ID	Description
PA-6877	Fixed an issue where a PingAccess upgrade from release 4.0 to release 4.2.1 was failing.

### **PingAccess 4.2.1 - December 2016**

PingAccess 4.2.1 is a cumulative maintenance release for PingAccess 4.2, which introduced several new features, including improved admin UI workflow, certificate trust chains, event storage in MS SQL, agent policy server failover, unknown resource handling, forward proxy handling, and installer support for upgrades. For more information, see the [release notes for PingAccess 4.2](#).

#### **Resolved issues**

Ticket ID	Description
PA-6436	Fixed an issue where configured sites were unreachable after upgrade to PingAccess 4.2, build 4.2.0.6.
PA-6317	Fixed an issue where, in a clustered environment using admin SSO, if the admin console is configured to use a proxy, and if the admin replica is not configured to use a proxy, admin SSO would not succeed in a failover situation.
PA-6408	Fixed an issue where you could not add a new row to a content rewrite rule via the UI.

### **PingAccess 4.2 - December 2016**

#### **Enhancements**

##### **Improved Admin UI workflow**

Improved configuration workflow that allows you to easily configure required elements without navigating away from a page or losing information.

##### **Certificate trust chains**

This feature allows you to add or modify a certificate chain by adding or removing intermediate and root certificates.

##### **Audit event storage in MS SQL 2012 & 2016**

Configure PingAccess to store logs in MS SQL Server 2012 & 2016.

##### **Agent policy server failover**

Configure a failover host and port on an agent definition to enable agent failover to a backup policy server in the event of a failure of the primary policy server.

##### **Unknown resource handling**

Specify handling of resources for which there is no configured application. This feature allows you to customize error pages for unknown resources and to enable request pass-through for PingAccess agents. This feature is useful when specifying a policy for an agent protected resource that has both secure and public content within the scope of the agent.

##### **Forward proxy support for outbound calls**

Specify and configure a forward proxy that may be required to make outbound calls.

##### **Installer support for upgrades**

You can now install and upgrade PingAccess on Windows and RHEL using the applicable installer package.

**Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
PA-3407	Fixed an issue that caused poor performance on reload when there are applications with many groovy script rules.
PA-4671	Improved handling of unsupported Content-Types during POST preservation.
PA-5400	Fixed an issue where an exception was incorrectly added to logs during evaluation of an OAuth Attribute Rule on an unprotected API application.
PA-5405	Fixed an issue where an exception was encountered by the error response handler if the connection to PingFederate is misconfigured.
PA-5448	Fixed an issue where a session cookie was not reissued if a transaction failed.
PA-5500	Fixed an issue with the display of values when viewing an Identity Mapping in expanded view.
PA-5502	Fixed an issue that caused upgrades to fail under certain conditions.
PA-5538	Fixed an issue where Save and Discard Changes buttons were not visible when adding or making changes to IP Source or Host Source settings on the HTTP Requests page.
PA-5644	Fixed an issue where expired tokens were logging incorrect error messages.
PA-5791	Improved handling of errors that were occurring when trying to decrypt a state parameter with a key that no longer exists.
PA-6027	Fixed an issue where warning messages weren't being parsed correctly.
PA-6271	Fixed an issue where upgrades were failing because the target instance admin console was not responding.
PA-6273	Fixed an issue where runtime requests were failing when using Internet Explorer 9 or 10.

**PingAccess 4.1.4 - March 2019**

PingAccess 4.1.4 is a cumulative maintenance release for PingAccess 4.1, which introduced several new features, including support for standards-based OpenID Connect provider login, JWT based identity mapping, OAuth 2.0 token introspection, and session timeout synchronization with PingFederate. For more information, see the [release notes for PingAccess 4.1](#).

**Resolved issues**

<b>Ticket ID</b>	<b>Description</b>
Multiple	Fixed potential security issues.

**PingAccess 4.1.3 - November 2016**

PingAccess 4.1.3 is a cumulative maintenance release for PingAccess 4.1, which introduced several new features, including support for standards-based OpenID Connect provider login, JWT based identity mapping, OAuth 2.0 token introspection, and session timeout synchronization with PingFederate. For more information, see the [release notes for PingAccess 4.1](#).

**Resolved issues**

Ticket ID	Description
PA-6014	Fixed an issue where the Upgrade Utility was not migrating the configuration for 3rd party OAuth server or 3rd party OIDC provider.
PA-6213	Fixed a potential security issue.

### PingAccess 4.1.2 - October 2016

PingAccess 4.1.2 is a cumulative maintenance release for PingAccess 4.1, which introduced several new features, including support for standards-based OpenID Connect provider login, JWT based identity mapping, OAuth 2.0 token introspection, and session timeout synchronization with PingFederate. For more information, see the [release notes for PingAccess 4.1](#).

#### Resolved issues

Ticket ID	Description
PA-5681	Fixed an issue where Heartbeat URL displays a blank page when Detailed Response is disabled.
PA-5828	Fixed an issue where agents using the same agent certificate would generate an IllegalStateException when replicating to a cluster of engines.
PA-5830	Fixed an issue where Identity Mappings no longer shows multiple attributes with the same name when there is a only difference in case.
PA-5876	Fixed an issue where the agentCacheInvalidatedResponseDuration field is incorrectly set to 0, causing the vnd-pi-cache-invalidated header to be missing from the agent response.
PA-5879	Fixed an issue where the vnd-pi-sub header is missing from the agent response.

### PingAccess 4.1.1 - September 2016

PingAccess 4.1.1 is a cumulative maintenance release for PingAccess 4.1, which introduced several new features, including support for standards-based OpenID Connect provider login, JWT based identity mapping, OAuth 2.0 token introspection, and session timeout synchronization with PingFederate. For more information, see the [release notes for PingAccess 4.1](#).

#### Resolved issues

Ticket ID	Description
PA-5665	Fixed an issue where you could not save changes to a Trusted Certificate Group.
PA-5654	Fixed an issue where upgrade would fail to migrate Authentication Requirements Rules.
PA-5651	Fixed an issue where a new Authentication Requirements Rule could not be created after upgrading to version 4.1.
PA-5646	Fixed an issue where RuleSets were always evaluated before Rules.
PA-5563	Fixed an issue where Admin API transaction logs were appearing in agent_audit_log and engine_audit_log tables when using the Log4j2 JDBCAppender.

Ticket ID	Description
PA-5556	Fixed an issue with Log4j2 JDBCAppender where a memory leak would create out of memory issues and log events were not added to the failover log file.
PA-5547	Fixed an issue with Engine and Agent Audit Logging where FailedRule entries were not appearing in logs.
PA-5451	Fixed an issue where a change to enable Skip Hostname Verification would not take effect until a restart of PingAccess.

## PingAccess 4.1 - August 2016

### Enhancements

#### Support for standards-based OpenID Connect provider login

PingAccess 4.1 introduces support for the use of a standards-based OpenID Connect provider as a source for authentication tokens.

There are several requirements and prerequisites that must be fulfilled before enabling this feature, including:

- All existing applications must be disabled prior to changing the token provider
- Only Basic Authentication for the administrator console must be enabled. Administrator SSO must be disabled.
- The third-party OpenID Connect token provider must support OpenID Connect issuer discovery

Once the token provider is switched, applications can be re-enabled, and Administrator SSO can be re-enabled. We recommend that if Administrator SSO is provided, you enable administrative roles on the **Single Sign-On** tab of the **Admin Authentication** configuration page and configure **required Administrator Attributes** to ensure that only administrators are permitted access to the administrative console.

To change the token provider type, navigate to **Settings > System > Token Provider**, then click **Change Token Provider Type**.

**Note:** This feature only works with web applications protected by PingAccess; API applications are not supported, and cannot be enabled if they exist in the configuration.

#### Ability to create identity mappings based on contents of a JWT

Identity mappings can now be added as claims to a signed JWT as well as in HTTP request headers to the back-end server. These JWTs are signed using the issuer information set in **Settings > Access > Auth Token Management**. The token itself can be validated using the `/pa/authtoken/JWKS` endpoint.

## OAuth 2.0 Token Introspection

[RFC7662](#) introduced a standard for querying an OAuth authorization server about the state of an OAuth 2.0 token and to determine meta-information about it.

This release of PingAccess provides an option to use the PingFederate 8.2 introspection endpoint.

**Note:** This feature requires the use of PingFederate 8.2, and it only applies to API applications.

Enable Token Introspection by navigating to **Settings > System > Token Provider > OAuth Resource Server > Use Token Introspection Endpoint**.

## PingFederate session timeouts can be synchronized with PingAccess

PingAccess now provides a means for PingFederate 8.2 to synchronize its session timeouts with PingAccess.

## Resolved issues

Ticket ID	Description
PA-4886	Fixed an issue when trying to generate a CSR for a certificate that includes a DNS name subject alternative name that starts with a wildcard (*).
PA-4230	Fixed an issue where Agent name can be invalid Unicode characters in HTTP headers.
PA-5306	Fixed an issue when configuring sites with MutualTlsSiteAuthenticator.
PA-5303	Fixed an issue where the status icon no longer appears for the replica administrative node.
PA-4892	Fixed an issue where a socket is not properly closed on error.
PA-4891	Fixed an issue where a socket is not properly closed on error.
PA-4882	Fixed an issue where the callback endpoint always returns a Forbidden when combining a Code WebSession and the use of X-Forwarded-Host.
PA-4878	Removed libraries that are no longer in use.
PA-4866	Fixed an issue where some plugin fields were not accepting input.
PA-4610	Modified run scripts to use <code>/dev/random</code> for cryptographic processing.
PA-4581	Fixed an issue where a slow backend site causes PingAccess to throw an OOM (Out of memory) exception.
PA-3429	Fixed an issue where local DB was not being set to a known state before applying replicated configuration.

## PingAccess 4.0.5 - March 2019

PingAccess 4.0.5 is a cumulative maintenance release for PingAccess 4.0, which introduced many new features, such as contextual authentication, WebSocket support, and a new administrative UI. For more information, see the [release notes for PingAccess 4.0](#).

## Resolved issues

Ticket ID	Description
Multiple	Fixed potential security issues.

### PingAccess 4.0.4 - July 2016

PingAccess 4.0.4 is a cumulative maintenance release for PingAccess 4.0, which introduced many new features, such as contextual authentication, WebSocket support, and a new administrative UI. For more information, see the [release notes for PingAccess 4.0](#).

#### Resolved issues

Ticket ID	Description
PA-5115	Resolved an issue with the automatic creation of configuration archives when the administrator logged in if the administrator authentication used Admin SSO.
PA-5189	The PingAccess Upgrade Utility no longer overwrites the certificate alias attribute with a GUID during an upgrade.

### PingAccess 4.0.3 - May 2016

PingAccess 4.0.3 is a cumulative maintenance release for PingAccess 4.0, which introduced many new features, such as contextual authentication, WebSocket support, and a new administrative UI. For more information, see the [release notes for PingAccess 4.0](#).

#### Resolved issues

Ticket ID	Description
PA-4862	Corrected an issue where upgrading an environment that has Admin SSO enabled could result in an admin authentication loop.
PA-4867	Addressed a potential security issue.
PA-4875	Fixed an issue where paginated collections of entities (sites, applications, etc.) could cause the administrative UI to hang while reloading.
PA-4877	Addressed an issue in the Windows service configuration that could impact performance.
PA-4889	Resolved a conflict between using the <code>code</code> OpenID Connect Login Type setting and the use of <code>X-Forwarded-Host</code> headers. In this situation, the <code>X-Forwarded-Host</code> value was not matching the PingFederate <code>redirect_uri</code> tied to the authorization code, and authentication would fail.

### PingAccess 4.0.2 - April 2016

PingAccess 4.0.2 is a cumulative maintenance release for PingAccess 4.0, which introduced many new features, such as contextual authentication, WebSocket support, and a new administrative UI. For more information, see the [release notes for PingAccess 4.0](#).

#### Resolved issues

Ticket ID	Description
PA-4639	Fixed a defect that prevented database audit logging from working.

Ticket ID	Description
PA-4635	Corrected an issue where changes to the <b>Update Token Window(s)</b> setting in the web sessions configuration did not persist.
PA-4627	Addressed an issue that could cause the logging buffer to fill, preventing PingAccess from processing requests.
PA-4604	For backchannel OAuth validation requests to PingFederate, the effective URL of the request is used. This effective URL now includes the URL scheme.
PA-4423	When parsing Set-Cookie header values, PingAccess now uses the <code>pa.uri.strict</code> property in <code>run.properties</code> in determining whether to allow or deny invalid characters in the query.

### PingAccess 4.0.1 - March 2016

PingAccess 4.0.1 is a cumulative maintenance release for PingAccess 4.0, which introduced many new features, such as contextual authentication, WebSocket support, and a new administrative UI. For more information, see the [release notes for PingAccess 4.0](#).

### Resolved issues

Ticket ID	Description
PA-4602	Fixed an issue where editing a resource would remove policies assigned to that resource.
PA-4598	Addressed an issue where the PingAccess Upgrade Utility would reset agent shared secrets.
PA-4416	Modified logging so expired tokens do not generate ERROR or WARN level log messages, since token expiration is an expected and normal operational condition.
PA-4415	Modified logging so responses from the Token Mediator Site Authenticator do not generate an INFO level message for every transaction.
PA-4232	When a % character appears in a URI processed in some way by PingAccess, if the character is not clearly part of a URL-encoded string, PingAccess treats it as a literal % character, and URL-encodes it as %25 for processing.

### PingAccess 4.0 - February 2016

#### Enhancements

##### Contextual authentication

PingAccess 4.0 introduces the Authentication Requirements rule type. Authentication Requirements rules define the type of authentication required to gain access to a web application, allowing for step-up authentication for access to more sensitive parts of an application. Additionally, requirements can be combined with other access control criteria to enable contextual authentication use cases, such as re-evaluating a user's authentication status if they move to an untrusted network, or using attribute values to trigger a requirement for a stronger form of authentication.

<b>WebSocket security</b>	Applications that use the WebSocket protocol can now be protected by PingAccess, allowing PingAccess access control policies and processing rules to be used to enhance security. WebSocket-based applications are supported by PingAccess as a gateway or when using PingAccess agents.
<b>New administrative user interface</b>	PingAccess 4.0 includes a completely redesigned administrative user interface, providing a uniform administration experience for PingAccess, PingFederate, and PingOne administrators..
<b>Auditor and administrator roles</b>	PingAccess 4.0 introduces role-based access control for administrative interfaces. Users can be assigned to the Administrator role, allowing full access to view and change the PingAccess configuration, or they can be assigned to the Auditor role, which allows read-only access to the configuration. Role-based access control is applied for both Admin SSO to the administrative UI or OAuth authentication to access the administrative API.
<b>New REST API version</b>	The PingAccess REST APIs have been updated to version 2, bringing a number of enhancements to that administrative interface. See <a href="#">Administrative API updates</a> on page 43 for detailed information about these changes and how to migrate to the new API version.
<b>New logging system</b>	<p>PingAccess now uses log4j2 as the logging engine. As a consequence, you will need to migrate your existing blitz4j configuration to log4j2.</p> <p>This change also brings several other enhancements, such as failover logging capabilities, improved logging performance, and the ability to have changes to the log level applied without requiring a restart of PingAccess.</p>
<b>Oracle JRE support</b>	PingAccess 4.0 removes the need to deploy the full Oracle JDK on runtime servers. Oracle JRE provides all required services.
<b>Windows and RHEL installers</b>	<p>We've now created an MSI-based installer for Windows and a CLI-based installation script for RedHat Enterprise Linux to simplify the installation of PingAccess.</p> <p>Both installers guide you through the installation decision points with a wizard-style interface, and update the PingAccess configuration based on those decisions.</p>
<b>Upgrade utility</b>	The Upgrade Utility is now the only tool required for performing upgrades, regardless of the source and target versions of PingAccess.

The PingAccess Upgrade Utility has also been enhanced to support migrating plugins developed with the Addon SDK.

## Other enhancements

There are numerous other usability and functionality enhancements in this release of PingAccess, including:

- In the PingAccess administrative user interface, **Description** fields have been added or modified such that they are now available and consistent across agent, engine, and application entities. These fields all support multi-line values, and entering their values is optional.
- In the PingAccess administrative console UI, the **Use Target Host Header** field is now cleared by default. The recommended practice is to send the public host header to the backend site.
- The administrator is now notified in the administrative user interface when PingAccess needs to be restarted after certain configuration changes.
- The Windows service name and description properties in `PA_HOME/sbin/windows/PingAccessService.conf` is now in the following format:

```
# Display name of the service

wrapper.ntservice.displayname=PingAccess
Service
# Description of the
service

wrapper.ntservice.description=PingAccess
Service
```

- PingAccess validates the web session's configured cookie domain to ensure it does not conflict with any virtual hosts associated with the applications the session assigned to.
- A unique nonce cookie name is now generated, rather than reusing the same name, resolving a potential issue if multiple authentication requests are generated prior to being handled by PingFederate.
- URI fragments are now preserved through the authentication process when a user is forced to re-authenticate to a resource.
- Administrators can now create localized error messages for user-facing error pages displayed by PingAccess.
- For the Rewrite Cookie Domain rule and the Rewrite Response Header rule, administrators can now specify that the public-facing cookie domain or URI path be rewritten for all site target

hosts, rather than needing to create a rule for each target host.

- The Content Rewrite rule now supports rewriting content from applications that do not specify a `Content-Type` header.
- The OAuth Attribute Value rule now supports multiple attributes and values, making it consistent with the Web Session Attribute rule.
- Error messages can now be defined based on the application the user accessed in addition to a generic system-wide message being used.
- Added validation to prevent a misconfiguration that could result in an authentication loop. Administrators need to be aware that the web session cookie will be sent to the configured domain. As part of the feature, validation is done in the admin console to prevent administrators from defining an invalid cookie domain.

## Resolved issues

Ticket ID	Description
PA-242	Validation for Groovy Rules that use inapplicable matchers
PA-1099	Fixed Database decryption bug
PA-1900	Fixed PingAccess Agent Protocol compliance issue
PA-1903	Scripts not using JAVA_HOME to locate Java installation
PA-2362	Token Mediation deleting 3rd party cookies
PA-2419	Fixed session expiration response
PA-2430	Fixed upgrade utility NPE when target PingAccess fails to start
PA-2696	OAuth Groovy Script Rule Is Not Executing During Response Processing
PA-2727	Improved PingAccess core processing to increase server stability.
PA-2815	Fixed Admin API validation issue
PA-2897	Stale post preservation cookie results in Internal Server Error from PA
PA-2899	Backup on authentication not created when using Admin SSO
PA-2900	Improved behavior when empty post body is sent to agent
PA-2907	Fixed error when OIDC token is revoked
PA-2926	Fixed admin re-authentication handling
PA-2950	Fixed NPE caused by specific Admin API call
PA-2972	Fixed NPE caused by specific Admin API call
PA-2974	PingAccess fails to start (on first attempt) on Windows
PA-2979	Fixed Admin UI NPE when importing CSR
PA-3008	Enhanced handling of values in imported keypairs to handle non-string SANs.
PA-3039	POST preservation fails with exception if *:3000 virtual host not defined

Ticket ID	Description
PA-3053	PingAccess linux service script doesn't work with non-root user
PA-3054	ehcache WARN level log messages in pingaccess.log on startup
PA-3101	PingFederate authorization server showing up as blank in admin UI
PA-3205	PUT requests where the request body is no longer available after an initial failure are no longer retried.
PA-3217	Admin replica failover does not take effect until after replica restart
PA-3224	OAuth Rule Deny Returns 401 to Client but Logs in Audit Log as 403
PA-3227	Unauthenticated response connection is not closed properly
PA-3253	Web session cookie domain needs validation against associated application / virtual hosts
PA-3293	The PingAccess Upgrade Utility now uses the address defined in the source PingAccess server's admin.bindAddress configuration.
PA-3329	Web Session edit requires re-entry of Client Secret
PA-3359	Secrets in /sharedSecrets not obfuscated by Admin API
PA-3398	Improvements have been made to the API responses so that they're not HTML-escaped, resolving occasional issues encountered with the configuration import and export functionality.
PA-3454	Web Session Data integrity violation when trying to change a web session name with one that already exists
PA-3469	500 internal server error returned if Protocol Source Header Name too long
PA-3480	Editing Rule Sets allows OAuth rules to be applied to Web Application
PA-3509	vnd-pi-resource cache grows unbounded
PA-3574	Reload race condition causes intermittent failure of reload
PA-3635	Off-by-one errors in header size and count limits
PA-3663	NPE if you try to save Rule with empty error response code
PA-3669	Introduced the pa.site.tls.sni.legacyMode configuration parameter to give the administrator control over how SNI server_name is set.
PA-3692	PingAccess no longer throws an exception when POST preservation data cannot be retrieved.
PA-4160	User is able to add the same cert multiple times to same Trusted Cert Group
PA-4197	Inline field error message not displayed
PA-4215	NPE when trying to Import CSR Response
PA-4219	Resolved an issue where POST Preservation used in conjunction with the Rewrite Content rule, a null pointer exception could occur.
PA-4234	RuleSet allows SuccessCriteria of SuccessIfAnyOneSucceedsLastHandlesError
PA-4244	Network Range Plugin: Error Response Content-Type should be required
PA-4453	PostPreservation pi.postsrv claim is not being cleared after encoded post
PA-4504	On startup, PF back-channel failover is broken

### Administrative API updates

With PingAccess 4.0, the administrative API interface has been updated to version 2. This means there were some fairly significant changes in some of the API endpoints.

Administrators who have written code that uses the API endpoints to automate administrative tasks will need to update their code to use the new endpoints.

**Note:** The fundamental change in all administrative API calls will be a change in the endpoint URI from `/pa-admin-api/v1` to `/pa-admin-api/v2`. For example, if you made a call to `/pa-admin-api/v1/pingfederate/admin`, your code would need to be updated to point to `/pa-admin-api/v2/pingfederate/admin`

The following table identifies specific API changes that may need more updates than just the path to the API endpoint.

Endpoint	Change Description	How to Update
<code>/pingFederateAdmin/accessTokens</code>	This endpoint now accepts an <code>encryptedvalue</code> or a <code>value</code> . The <code>encryptedvalue</code> is a string that contains an obfuscated value, as obfuscated when using the <code>obfuscate.sh</code> script.	In the v1 API, the model template includes a <code>clientSecret</code> property. This is now replaced with a <code>clientSecret</code> property with a subschema that can contain either an <code>encryptedValue</code> string or a <code>value</code> string.
<code>/webSession</code>	The name of this endpoint has been changed to <code>/webSessions</code>	Modify any code that accesses the v1 <code>/webSession</code> endpoint to point to <code>/webSessions</code> instead.
<code>/webSessions</code>	As with the <code>/pingFederateAdmin/accessTokens</code> endpoint, the <code>/webSessions</code> endpoint now supports either an <code>encryptedValue</code> or a <code>value</code> .	This change is the same as for the <code>/pingFederateAdmin/accessTokens</code> endpoint.
<code>/auth/oauth</code>	As with the <code>/pingFederateAdmin/accessTokens</code> endpoint, the <code>/auth/oauth</code> endpoint now supports either an <code>encryptedValue</code> or a <code>value</code> .	This change is the same as for the <code>/pingFederateAdmin/accessTokens</code> endpoint.
<code>/auth/basic</code>	When the <code>GET</code> method is used with this endpoint, it now returns whether basic authentication is enabled or disabled. Deprecated fields are no longer returned.	If your code performs actions based on the v1 response body for <code>GET</code> requests, it will need to be modified.
<code>/applications/{id}</code>	Removed the <code>resourceIds</code> array, as they are not managed as part of the <code>applications</code> endpoint, but instead are managed through the <code>/applications/{id}/resources</code> endpoint.	Code that depends on the <code>resourceIds</code> array returned by the <code>GET</code> method will need to be updated.
<code>/applications</code>	The <code>virtualHostId</code> property has been removed.	Use the first value in the <code>virtualHostIds</code> array instead.

Endpoint	Change Description	How to Update
/sites	The <code>host</code> and <code>port</code> fields have been combined into the <code>targets</code> array. These values were used in older versions of PingAccess, when a single target was defined for a Site object.	Update your code to use the <code>targets</code> array. Each element in this array is a <code>host:port</code> pair.
/sharedSecrets, /engines, and /adminConfig/replicaAdmins	These three endpoints have been updated to allow their respective configurations to be individually exported and imported.	This is new functionality; no changes to existing code is required.
/users	<p>This endpoint has been updated to facilitate future use of multiple users for basic authentication. In the v1 API, changes made through this endpoint applied to the Administrator user, as that was the only user. Changing passwords or toggling the <code>slaAccepted</code>, <code>firstLogin</code>, and <code>showTutorial</code> settings were handled through this endpoint.</p> <p>In the v2 API, the <code>GET</code> method on <code>/users</code> returns a user list, but the following additional endpoints have been created:</p> <ul style="list-style-type: none"> <li><code>/users/{id}</code></li> <li><code>/users/{id}/password</code></li> </ul> <p>A <code>GET</code> request to the first of these returns information for the specified user.</p> <p>A <code>PUT</code> to the first allows the user flags to be manipulated as they would have been in the <code>/users</code> endpoint in v1 of the API.</p> <p>To change the user password, use a <code>PUT</code> request on the second endpoint, specifying the old and new passwords in the payload.</p>	Code that uses the <code>/users</code> endpoint will need to be updated to use the new endpoints. Where it was possible in the v1 API to change the flags and the password with a single API call, two calls now will need to be used - the first to <code>/users/{id}</code> , and the second to <code>/users/{id}/password</code> .

### PingAccess 3.2.6 - February 2016

PingAccess 3.2.6 addresses the following issues:

#### POST Preservation

PingAccess no longer throws an exception when POST preservation data cannot be retrieved.

#### PUT requests with On-Demand availability profiles

PUT requests where the request body is no longer available after an initial failure are no longer retried.

#### Server Name Indication

Corrected a `server_name` and `host` data/header mismatch when using SNI.

**Non-string Subject Alternative Name values in imported keypairs**

Enhanced handling of values in imported keypairs to handle non-string SANs.

**Admin console not accessible after upgrade**

Corrected an issue where an upgrade could result in the administrative console not being accessible.

**Security fix**

Fixed a security vulnerability (SECADV012).

**PingAccess 3.2.5 - December 2015**

PingAccess 3.2.5 addresses the following issue:

**Issues resolved:**

Corrected a resource allocation issue when using PingAccess agents configured with caching enabled in the agent.

**PingAccess 3.2.4 - December 2015**

PingAccess 3.2.4 addresses the following issues:

**Authentication loop with cached user attributes**

Resolved an issue where a misconfiguration in the web session user attribute caching settings could cause an authentication loop.

**Security updates**

Fixed a few minor potential security issues.

**Improved expiration handling for AccessToken validation during API flow**

When validating an access token in the API flow which did not contain an `expires_in` value, a null pointer exception would be thrown.

**PingAccess 3.2.3 - October 2015**

PingAccess 3.2.3 addresses the following issues:

**Security issues**

Two minor potential security issues are addressed in this release.

**Fixed upgrade utility `SSLHandshakeException` failures with Java 8 update 51 or later**

When updating from versions of PingAccess that use deprecated RC4 ciphers, the PingAccess Upgrade Utility would fail.

**Fixed potential issues with POST preservation in certain configuration scenarios**

In certain rare cases, POST preservation would fail as a result of a configuration error. Additional checks have been added to prevent these configuration errors from occurring.

**Fixed issue that could lead to unexpected request failures when using token mediation**

If a protected application relies on cookies being sent with the mediated token, if the token mediation flow needed to retry, the additional cookies delivered with the token would be removed, resulting in unexpected application failures.

**Fixed issue where the Subject Alternative Name is missing from the CSR for key pairs created in PingAccess**

When a key pair was generated in PingAccess and a Certificate Signing Request was issued, the CSR was missing the Subject Alternative Names.

**Improvements to the `install-service.bat` script**

When executed from a directory with a space in the path, the `install-service.bat` script would fail. This script has been updated to correct the issue.

**Made the `dbfilepasswd` and `dbuserpasswd` scripts more robust**

These scripts now run from paths containing spaces, and use the Java executable identified by `JAVA_HOME`.

**Added validation to prevent a potential redirect loop**

When a web session cookie domain is configured incorrectly, a user's browser could end up in an endless redirection loop. PingAccess now includes additional validation to prevent this misconfiguration.

**PingAccess 3.2.2 - August 2015**

PingAccess 3.2.2 addresses the following issues:

**The Admin API should require authnReqListId be set to 0 for an anonymous user**

Authentication requirements should not be allowed to be added to an anonymous resource. The PingAccess UI enforces this constraint, but previously the Admin API did not.

**Configuration backup archive not created when using Admin SSO**

When an administrator user logs into the administrative console using SSO authentication, PingAccess does not create a configuration archive. The archive is created successfully when the administrator logs in using basic authentication.

**Unable to reorder PingAccess rules inside Rule Sets in UI**

Making a change in the order of rules within a Rule Set produces a success message, but after navigating to another page and returning to the Policy page, the rules are displayed in the previous order, as it was before the change.

**JWT signature error produced when integrating with PingFederate 7.2**

When using unsigned access tokens with PingAccess 3.2, authentication using the OpenID Connect authentication flow may fail, logging the following message in `<PA_HOME>/log/pingaccess.log` when logging is set to `DEBUG`:

```
The JWT has no signature but the JWT
Consumer is configured to require
one
```

**After Admin Console cookie expiration, the administrator is prompted for basic authentication instead of SSO**

The problem occurs when Admin SSO is enabled and the administrator is logged into the Admin Console, but the access cookie has expired, for example, due to no user activity for a certain time period. In this case, the Admin Console directs the user to the basic login prompt instead of to PingFederate for reauthentication using SSO.

**Concealed plugin fields are not handled correctly in the PingAccess UI**

When entering values in the Basic Authentication Site Authenticator form, if username and password values are filled and then the username is edited again, the password value is saved as null rather than the password value entered. This issue affects any plugin with a concealed field such as a password field.

**New login required after change to the Admin SSO page even though SSO is disabled**

If the administrator changes the **Client ID** value in the Admin SSO page, but does not select the **Enabled** checkbox, the administrator is required to authenticate again. A new login should be required only if Admin SSO is enabled.

### **Admin SSO authentication fails when PingAccess 3.2 is installed with PingFederate 7.2**

When PingAccess 3.2 is used with PingFederate 7.2, Admin SSO does not work.

### **PingAccess load balancing not enforcing stickiness**

In some cases, PingAccess sticky sessions do not work with PingAccess load balancing.

### **Corrected a potential security vulnerability**

Refer to the Security Advisory SECADV010 on the [Customer Portal](#) for more information.

## **PingAccess 3.2.1 - July 2015**

PingAccess 3.2.1 includes the following fixes:

### **Stale `postprsv` Cookie Causes PingAccess Internal Server Error Response**

In certain circumstances when using POST Preservation, the `postprsv` cookie was not properly maintained, resulting in the cookie not containing the expected information.

### **Intermittent 403 Forbidden Responses when Browser Pre-fetches `favicon.ico`**

In some instances, a browser might attempt to retrieve `favicon.ico` before a session cookie was issued, resulting in access being denied to the resource.

## **PingAccess 3.2 - June 2015**

PingAccess 3.2 includes the following enhancements and new functionality:

### **Access Control Enhancements**

#### **Rate Limiting**

The **Rate Limiting** rule enables administrators to control the allowed request rate to a protected API or Web Application based on the identity, source IP address, OAuth client, or resource being accessed.

#### **New HTTP Request Rules**

The **HTTP Request Rule** has been refactored into two rules: The **HTTP Request Header** and **HTTP Request Parameter** rules. These rules provide additional flexibility for making policy decisions based on values passed either in HTTP headers sent by a client, or based on form data submitted by a client. Both of these new rule types can be configured to require multiple value matches.

#### **Cross-Origin Resource Sharing (CORS)**

Cross-Origin Resource Sharing is a method for allowing restricted resources on a web page to be requested from a domain that is different from the domain that hosts the requested web page. This release of PingAccess adds an access control rule that can be used to control this type of access request.

### **Engine Enhancements**

#### **HTTP and HTTPS Engine Listeners**

When multiple engine listeners are defined, PingAccess now allows the administrator to define, on a per-engine listener basis, whether the listener uses HTTP or HTTPS.

#### **Multiple Access Token Manager Support**

In instances where multiple Access Token Managers are configured in PingFederate to

provide OAuth access tokens for API applications, the `aud` OAuth parameter is populated with the user-requested URI to enable PingFederate to select the proper Access Token Manager when PingAccess makes a validation request to PingFederate.

## POST Preservation

When a user submits a POST form and the authentication session has timed out, the user is redirected to PingFederate in order to re-authenticate. The POST form data is now preserved through this redirection, and the submitted form is automatically resubmitted after successful authentication. The preserved POST form data can optionally be encrypted in the user's browser with this feature.

## HTTP Header-Based Load Balancing

In addition to the Round Robin load balancing strategy, PingAccess now includes a header-based load balancing strategy. This feature allows an external load balancer in the infrastructure to inject a header (such as `X-Target-Host`) with a value for a hostname or IP address (defined as a target in the Site configuration) where the request should be routed after PingAccess processes it.

## Improvements to HTTP Security Headers Set for PingAccess Admin/Engine/Agent Listeners

PingAccess now includes a number of HTTP Security Headers for connections to the Administrative User Interface, Engine, and Agents. These headers are defined using options in `run.properties`, and additional headers can be added if desired.

## Auditing Enhancements

### Auditing of Unknown Resource Requests

When a client requests a resource that is not known, PingAccess does not record the request in the audit log for performance reasons. In PingAccess 3.2, the optional configuration property `pa.auditing.unknown.resource` can be enabled in order to help troubleshoot resource definition issues.

### Request Tracking

Audit logging now includes a default option to include either a Tracking ID or an Access Token ID along with an Exchange ID to make it easier to follow the audit information for a particular session and exchange in the log files.

## Administrative Enhancements

### JSON-Based Export/Import of PingAccess Configuration

The existing **Backup** section for the administrative user interface has been replaced with a JSON-based export/import capability, making it simpler to duplicate an environment for development purposes. The JSON-based import functionality also simplifies the procedure to restore an

## Support for Wildcards in Virtual Hosts

environment's backup by allowing the administrator to use the administrative user interface.

Earlier releases of PingAccess permitted the use of a wildcard virtual host that would match any host (for example, \*:443), but wildcards used in conjunction with an existing domain name were not supported. This feature adds the ability to specify a wildcard host with a domain (for example, \*.example.com:443).

## Usability Enhancements

Several administrative interface usability enhancements are in this release, including:

- Moved Options to Advanced Sections on Some Configuration Pages
- Restructured the Settings Page
- Added Pagination, List View, and Filtering Options to Improve Administrative UI Scalability
- Test Connections to Sites and PingFederate When Saving Related Configuration
- Added Cluster Status Display Information to Clustering Configuration Page

## Administrative API Name-Based Search

When using the Administrative API at `/pa-admin-api/v1/` to retrieve information about named objects (for example, Agents or Engines), a `name` parameter can be specified to retrieve the object with the exact name specified.

## PingAccess 3.1 - February 2015

PingAccess 3.1 includes enhancements and new functionality for the Session Management capabilities, the PingAccess Engine, and the Administrative interface.

### Session Management

#### Session Attribute Updates and Revocation

Administrators can now configure PingAccess to periodically query PingFederate to update attributes associated with the session, and to terminate the session based on a determination by PingFederate that the user no longer meets the criteria used to issue a token. For example, if PingFederate is configured to return the user's attributes only if the user account is enabled, disabling the user account can now trigger a session revocation. Additionally, if a user is removed from a group that grants them access to an application, access can be denied for a current session.

#### Support for Large Attribute Data

PingAccess now has the ability to cache user attribute data that previously was limited to the browser maximum cookie size. When this feature is enabled, potentially large attribute values - such as group memberships - can be used in policy decisions.

#### OpenID Connect / OAuth 2.0 Form Post Response Mode

Support has been added for the emerging [OAuth V2 Form Post Response Mode](#) standard. If you are

upgrading from an earlier release of PingAccess, web sessions using the existing `POST` method will be migrated to `x_post`.

## Engine

### HTTP Request Configuration Source Handling

To better integrate PingAccess with configurations using reverse proxies and external load balancers, support has been added to support arbitrary IP Source, Host Source, and Protocol Source headers. This allows headers such as the **X-Forwarded-For** header to be injected by those reverse proxies in order to preserve information about the originating host IP address, hostname, and protocol source, in order to be able to use that information to make policy decisions. In addition, the originating host IP address is recorded in the audit logs.

### HTTP Response Body Content Rewriting

The new Rewrite Content Rule allows arbitrary content rewriting to be performed on outbound content. The content rewriting functionality can be used, for example, to rewrite URL text in HTTP responses so links a user might click on will use the external hostname for the Application rather than an internal name. This feature can also be constrained to particular content-types, allowing different rules to be tailored to the response `Content-Type` header.

### Multiple Engine Ports

The PingAccess Engine listener can now listen on multiple ports, providing greater configuration flexibility.

### Specify Different PingFederate Runtime Engines for Backchannel Calls

PingAccess can now use separate hostnames and ports to perform behind-the-scenes communication with PingFederate, providing greater flexibility in managing traffic between the two products. If more than one backchannel communication is set up, a built-in availability profile is used to provide failover.

## Administration

### Configurable Signature Algorithm Generated Key Pairs

When generating a key pair, the **Signature Algorithm** can now be selected, and the options available are based on the chosen **Key Algorithm**.

### Remove Resource Ordering

The determination of the "most specific" match of an application resource path has been simplified, removing the need for manual ordering of resources within an application. PingAccess now evaluates this based on the length of the path requested and matching that to the Path Prefixes defined in the Application. This change also removes the `PATCH` method from the `/applications/{id}/resources` Administrative API endpoint, since that method was used to update the order of Resources in an Application.

**Authentication Requirements for Admin SSO**

Authentication Requirements can now be specified for administrator Single Sign-On. This can be used to ensure administrative users log in with stronger forms of authentication than just a username and password.

**PingAccess 3.0 R2 - October 2014**

This release introduces the following new features:

**Backup Admin Console Nodes**

Provides the ability, in a clustered environment, to create a backup administrative node that the administrator can manually fail over to in the event of a catastrophic failure of the primary administrative node.

**Failover and Load Balancing for Sites**

Adds new functionality to provide failover and load balancing to multiple backend target servers without requiring a load balancer.

**Ability to Ignore HTTPS Certificate Errors**

Reduces certificate management burden for internal servers in a controlled environment by allowing the administrator to ignore certificate errors for backend connections, such as connections to Site targets.

**Heartbeat Endpoint Enhancements**

Enhances the monitoring capabilities by adding functionality to the heartbeat to return a configurable list of performance metrics as a JSON payload for consumption by third party monitoring tools.

**Logging Enhancements**

Adds logging options for rewritten cookies as well as cookies passed or proxied, and realign logged information with appropriate log levels.

**PingAccess 3.0.3 - November 2014**

This release addresses the following issue:

- Corrected a potential security issue in Identity Mappings (SECBL006)

**PingAccess 3.0.2 - September 2014**

This release addresses the following issue:

- Resolved an issue with Session Validation causing the token mediator to stop working.

**PingAccess 3.0.1 - August 2014**

This release addresses the following issues:

- Resolved an issue with token validation when using OAuth Admin API Authentication
- Corrected handling of PingFederate Runtime Base Path setting
- OIDC callback endpoint improvements to support front-end load balancers listening on a different port than the PingAccess Engine

**PingAccess 3.0 - July 2014****PingAccess Agents**

Added PingAccess Agents to provide additional architectural flexibility with an agent based deployment model.

**Session Management enhancements**

Web session management has been enhanced to offer additional security for end user-driven logout use cases.

**Add-on Java SDK**

New PingAccess add-on Java SDK has been introduced.

**TLS Server Name Indication support**

HTTPS listener configuration has been extended to support the TLS Server Name Indication (SNI) extension.

**Request/Response Time Auditing**

Additional fields have been added to the engine audit logs for performance monitoring and capacity planning purposes - total request processing time and back-end proxy response time.

**Administration enhancements**

Many enhancements have been made to improve the administration and modeling of configuration in PingAccess.

**PingAccess 2.1.4 – June 2014**

- Resolved an issue with Resource Ordering in the Administrative Console.
- improved interoperability with backend applications introduced by URL filtering in PingAccess 2.1.3.

**PingAccess 2.1.3 - May 2014**

- Fix a potential security issue that affects deployments that have varying policy applied across a single virtual server.

**PingAccess 2.1.2 – April 2014**

- Allow for specifying the base path for PingFederate. Useful when PingFederate is behind a reverse proxy.

**PingAccess 2.1.1 – March 2014**

- Fix Identity Mediation back channel communication issue.
- Fix Web Session cookie attribute handling.

**PingAccess 2.1 - December 2013**

- Ability to encrypt the PA session token.
- Sites can have multiple Site Authenticators configured.
- Added Authentication Requirements policy to allow step-up authentication to a Resource.
- Ability to specify “Any” or “All” processing to policy rules within a rule set.
- Multiple Web Sessions can be configured to scope a PingAccess session for a specific set of Resources.
- Added OpenID Connect Basic Profile flow for obtaining claims from PingFederate.
- Enhanced Audit log options to database and Splunk.

**PingAccess 2.0.1 - October 2013**

- Fixed well-known HTTP/S port issue
- Fixed a potential security issue with the Web Session Header Site Authenticator

**PingAccess 2.0 - September 2013**

- Initial General Availability (GA) release

**PingAccess 1.0 - April 2013**

- Limited release

# PingAccess Policy Migration Release Notes

---

## Release Notes

PingAccess Policy Migration (PAPM) simplifies Access Management infrastructure migration from CA SSO (Siteminder) and Oracle Access Manager (OAM) to PingAccess. PAPM enables the easy migration of policy and configuration from the existing system to PingAccess, allowing for easier configuration of PingAccess applications and policies while keeping existing policy behavior.

### PingAccess Policy Migration 2.0 - December 2018

#### Release details

- **PingAccess Policy Migration 2.0** is a new major release for PingAccess Policy Migration.
- **PingAccess Policy Migration 2.0** introduces several new features, including:
  - Policy Automation
  - Policy Testing
  - Monitoring Dashboard
- **PingAccess Policy Migration 2.0** removes support for Internet Explorer 11.

#### Resolved issues

- **PPAT-384:** Fixed an issue where an error was encountered during the import of migration data.

#### Known limitations

- The uploaded migration file name is hidden when using the IE11 or Edge browsers.
- PingAccess Policy Migration may create rule names that are too long to display in some versions of the PingAccess UI. These rule names may be replaced by an ellipsis.
- An error occurs when adding a PingFederate template if the connection is WS-Trust and browser SSO is not enabled.

#### Known issues

- PingAccess Policy Migration sets the application context root for migrated applications to /. Because each Virtual Host/Context Root combination must be unique, this prevents the creation of more than one application per virtual host.
- Deletion of an import file does not immediately remove the file from the file selection dropdown list.
- If PingAccess or PingFederate servers are not available when migrating configuration, the request may hang for a long time
- Audit record backups are archived as .txt files instead of compressed .csv files.
- PAPM will not migrate an application where the name contains a "/" character.
- UI elements may overlap if the browser width is below 1280 pixels. For optimal user experience, use a browser window size of 1280px x 1024px or larger.

### PingAccess Policy Migration 1.0.1 - August 2018

#### Release details

- **PingAccess Policy Migration 1.0.1** is a cumulative maintenance release for PingAccess Policy Migration 1.0, which was the first release of this product. For information on PingAccess Policy Migration 1.0, see the [release notes](#).

- **PingAccess Policy Migration 1.0.1** introduces an [upgrade utility](#) to allow for easy upgrade of PingAccess Policy Migration to the most recent version.

### Resolved issues

- **PPAT-101:** Fixed a potential security issue.
- **PPAT-365:** Fixed an issue where migration would fail if an agent configuration value exceeded 2000 characters.

### Known limitations

- The uploaded migration file name is hidden when using the IE11 or Edge browsers.
- PingAccess Policy Migration may create rule names that are too long to display in some versions of the PingAccess UI. These rule names may be replaced by an ellipsis.
- An error occurs when adding a PingFederate template if the connection is WS-Trust and browser SSO is not enabled.

### Known issues

- PingAccess Policy Migration sets the application context root for migrated applications to /. Because each Virtual Host/Context Root combination must be unique, this prevents the creation of more than one application per virtual host.
- Deletion of an import file does not immediately remove the file from the file selection dropdown list.
- If PingAccess or PingFederate servers are not available when migrating configuration, the request may hang for a long time
- Audit record backups are archived as .txt files instead of compressed .csv files.
- PAPM will not migrate an application where the name contains a "/" character.
- UI elements may overlap if the browser width is below 1280 pixels. For optimal user experience, use a browser window size of 1280px x 1024px or larger.

## PingAccess Policy Migration 1.0 - June 2018

### Release details

- This is the first release of this product.

### Known limitations

- The uploaded migration file name is hidden when using the IE11 or Edge browsers.
- PingAccess Policy Migration may create rule names that are too long to display in some versions of the PingAccess UI. These rule names may be replaced by an ellipsis.
- An error occurs when adding a PingFederate template if the connection is WS-Trust and browser SSO is not enabled.

### Known issues

- PingAccess Policy Migration sets the application context root for migrated applications to /. Because each Virtual Host/Context Root combination must be unique, this prevents the creation of more than one application per virtual host.
- Deletion of an import file does not immediately remove the file from the file selection dropdown list.
- If PingAccess or PingFederate servers are not available when migrating configuration, the request may hang for a long time
- Audit record backups are archived as .txt files instead of compressed .csv files.

- PAPM will not migrate an application where the name contains a "/" character.
- UI elements may overlap if the browser width is below 1280 pixels. For optimal user experience, use a browser window size of 1280px x 1024px or larger.

## Ping Identity Automated Deployment for AWS Release Notes

---

### Release Notes

These release notes summarize the changes in current and previous product updates.

The Ping Identity Automated Deployment for AWS allows you to deploy Ping Identity products to an Amazon Web Services VPC. This solution, both for customers with and without existing AWS resources, allows administrators to easily deploy and configure a functioning clustered environment for your Ping Identity product that includes load balancers, SSH access, and auto scaling functionality. Templates included with the package guide you through the setup of all necessary components, including the S3 bucket, EC2 instances, routing and security parameters, and naming conventions.

#### Release history

This section shows the release history for the Ping Identity automated deployment for AWS.

#### Release 1.0.1 - March 2018

- Modified templates to use S3 URLs that include the AWS region.
- Added the **Internal CA AMI ID** as a configurable parameter in the `create-pingaccess.yaml` and `pingaccess-deploy.yaml` templates.
- Added the **PingFederate AMI ID** as a configurable parameter in the `create-pingaccess.yaml` and `pingaccess-deploy.yaml` templates.

#### Release 1.0.0 - December 2017

- This is the first release of this product. This release supports the deployment of a full PingAccess cluster, as well as an optional PingFederate instance that is available for demonstration purposes.

#### Known issues and limitations

This section shows the known issues and limitations for the Ping Identity automated deployment for AWS.

##### Known issues

- There are no known issues in this release.

##### Known limitations

- The PingAccess for AWS solution cannot yet support agent deployments due to a limitation in the Amazon Elastic Load Balancer implementation.

## About PingAccess

---

### PingAccess overview

---

This document provides an overview of PingAccess. Use this document to gain an understanding of the product, to learn about what you can do, and to discover the many features it provides. To get the most from PingAccess, users should read about and understand the concepts included in this document.

As you learn about PingAccess features and functions, review PingAccess scenario documentation for steps to configure them. For a comprehensive set of instructions for using the PingAccess interface, see the *PingAccess User Interface Reference Guide*.

This document answers the following questions:

- [What is PingAccess?](#) on page 56
- [What can I do with PingAccess?](#) on page 57
- [How does PingAccess work?](#) on page 59
- [What can I configure with PingAccess?](#) on page 60

## What is PingAccess?

---

PingAccess is an identity-enabled access management product that protects Web Applications and APIs by applying security policies to client requests. In simpler terms, PingAccess allows you to protect sites, APIs, and other resources using rules and other authentication criteria. It works in conjunction with PingFederate or other common token provider via the OAuth 2.0 and OpenID Connect protocols to integrate identity-based access management policies via a federated corporate identity store using open standards access protocols.

## PingAccess for Azure AD

---

PingAccess for Azure AD is a free version of PingAccess for users of Microsoft's Azure AD that allows you to protect up to 20 applications. The goal of this solution is to allow for greater control over the access to legacy on-premise applications through the use of PingAccess Identity Mapping functionality.

This free version includes a limited feature set that is intended to support the basic requirements for application protection using this solution. Users of PingAccess for Azure AD are able to upgrade to a full license that will allow the use of the full PingAccess feature set.

**Important:** When your PingAccess for Azure AD license expires, access to the admin API is removed and you are unable to configure the product. Though managed access to configured applications continues, you must upload a new license file before you can make any additional configuration changes.

**Upgrade notice:** PingAccess for Azure AD provides a limited feature set that may not be compatible with existing PingAccess configurations. For this reason, upgrading from an earlier full version of PingAccess to PingAccess for Azure AD is **not supported**.

The following table details the available functionality on each of the PingAccess versions, both in the PingAccess user interface and the API.

Functionality	PingAccess	PingAccess for Azure AD
Create applications	Yes	Limited to 20 web session applications.
Create site authenticators	Yes	Limited to Basic and Mutual TLS.
Configure identity mappings	Yes	Limited to Header and JWT.
Create load balancing strategies	Yes	Limited to Header-Based and Round Robin.
Configure web sessions	Yes	Limited to web sessions with OIDC login type CODE.
Configure token provider	Yes	Limited to Microsoft Azure AD authentication source.

Export/Import configuration	Yes	Limited to configurations that includes only features permitted by license type.
Configure policies	Yes	No
Specify authentication requirements	Yes	No
Create and configure custom plugins using the SDK	Yes	No
Configure sites	Yes	Yes
Configure agents	Yes	Yes
Create virtual hosts	Yes	Yes
Configure unknown resource handling	Yes	Yes
Configure availability profiles	Yes	Yes
Configure HTTP request handling	Yes	Yes
Configure listeners	Yes	Yes
Configure forward proxy settings	Yes	Yes
Manage certificates	Yes	Yes
Manage key pairs	Yes	Yes
Configure administrator authentication	Yes	Yes
Configure clustering	Yes	Yes
Manage licenses	Yes	Yes

## What can I do with PingAccess?

---

PingAccess provides a highly customizable solution to identity access management that allows you to control access in a variety of ways by specifying a wide range of conditions that must be satisfied. Read the following sections to discover the methods PingAccess uses to control access and perform system functions. To learn more about the configuration required for any of the following topics, see PingAccess configuration scenarios on [support.pingidentity.com/s/documentation](https://support.pingidentity.com/s/documentation).

The main functionality of PingAccess is to allow you to protect an application or API. You can:

- Use PingAccess to protect the application and API resources to which client requests are forwarded.
- Partition applications for tighter access control through the use of resources.
- Customize configuration of site authenticators and authentication requirements to suit the security needs of your organization.
- Incorporate legacy authentication mechanisms through Token Mediation.
- Apply policies to define how and when a client can access target resources.

Customize your identity access management configuration with the following features.

### Apply policies

Use policies, made up of rules, set of rules, or groups of rule sets applied to an application and its resources, to define how and when a client can access target sites. Rules are the building blocks for access control and request processing.

### **Backup and restore**

Backup or restore a PingAccess configuration with just a few clicks.

### **Configure a token provider**

PingAccess can be configured to use PingFederate as the token provider or may be configured to use a common token provider via the OAuth 2.0 or OpenID Connect protocols.

### **Configure administrator authentication**

Allow administrators to authenticate with a simple username and password, or configure them to authenticate via SSO or API in conjunction with PingFederate.

### **Configure advanced network settings**

Create an availability profile to determine how you want to classify a target server as having failed, configure listener ports, define a load balancing strategy, or use HTTP Requests to match a served resource with the originating client.

### **Configure logging**

Capture several log types, including those for the engine, security auditing, and cookies. Store logs in Splunk, in an Oracle, PostgreSQL, or SQL Server database, or in a file.

### **Configure Single Logout**

End PingAccess sessions easily when used in conjunction with PingFederate managed sessions or compatible third party OpenID Connect providers.

### **Create clusters**

Deploy PingAccess in a clustered environment to provide higher scalability and availability for critical services. Use subclusters to provide better scaling of large PingAccess deployments by allowing multiple engine nodes in the configuration to share information. Place a load balancer in front of each subcluster in order to distribute connections to the nodes in the subcluster.

### **Customize PingAccess look and feel**

Customize and localize the PingAccess pages your users will see, including those for error messages and logout confirmation.

### **Customize with SDKs**

Customize development with SDKs to extend the functionality of the PingAccess server.

### **Manage certificates and key pairs**

Import certificates to establish trust with certificates presented during secure HTTPS sessions. Import or generate key pairs that include the private key and X.509 certificate required for HTTPS communication.

### **Manage sessions**

Use web sessions to define the policies for web application session creation, lifetime, timeout, and scope. Use multiple web sessions to scope the session to meet the needs of a target set of applications. Web sessions improve the security model of the session by preventing unrelated applications from impersonating the end user.

### **Manually configure runtime parameters**

Use a text editor to modify configuration file settings used by PingAccess at runtime.

### **Protect an application or API**

Use PingAccess to protect the application and API resources to which client requests are forwarded. Partition applications for tighter access control through the use of resources.

Customize configuration of site authenticators and authentication requirements to suit the security needs of your organization.

### Tune performance

Optimize a wide variety of PingAccess components for maximum performance.

### Upgrade an existing installation

Easily upgrade an existing installation using the installer, or more carefully manage the upgrade process with the PingAccess Upgrade Utility.

### Use APIs

Use the PingAccess APIs to provide a powerful configuration and management experience outside the PingAccess user interface.

## How does PingAccess work?

---

Access requests are either routed through a PingAccess Gateway to the target Site, or they are intercepted at the target web application server by a PingAccess Agent, which in turn coordinates access policy decisions with a PingAccess Policy Server. In either instance, policies applied to access requests for the target Application are evaluated, and PingAccess makes a policy-based decision to grant or deny access to the requested resource. When access is granted, client requests and server responses can be modified to provide additional identity information required by the target Application.

### WAM session initiation

When a user authenticates, PingAccess applies the application and resource-level policies to the request. Once policy evaluation is passed, any required token mediation between the back-end Site and the authenticated user is performed. The user is then granted access to the Site.

#### Processing steps:

1. When a user requests access to a Web resource from PingAccess, PingAccess inspects the request for a PingAccess Token.
2. If the PA Token is missing, PingAccess redirects the user to an OpenID Connect Provider (OP) for authentication.

**Info:** When using an OP, an OAuth Client must already be configured in PingAccess. For steps on configuring an OAuth Client within PingFederate, see the *PingFederate Administrator's Manual*. To configure the OAuth Client within PingAccess, see the PingAccess scenario to *Configure a Token Provider*.

3. The OP follows the appropriate authentication process, evaluates domain-level policies, and issues an OpenID Connect (OIDC) ID Token to PingAccess.
4. PingAccess validates the ID Token and issues a PA Token and sends it to the browser in a cookie during a redirect to the original target resource. Upon gaining access to the resource, PingAccess evaluates application and resource-level policies and optionally audits the request.

**Info:** PingAccess can perform *Token Mediation* by exchanging the PA Token for the appropriate security token from the PingFederate STS or from a cache (if token mediation occurred recently).

5. PingAccess forwards the request to the target site.
6. PingAccess processes the response from the site to the browser (step not shown).

**Info:** See the Session Management scenario for more information.

## Token mediation

When planning a PingAccess deployment, it is necessary to take inventory of existing applications, and their authentication requirements and mechanisms. When an existing token-based authentication mechanism is in use, retrofitting that mechanism may not always be desirable or cost-effective.

Token Mediation allows a PingAccess gateway to use a PingFederate token generator to exchange the PA Token or an OAuth Bearer Token for a security token used by the foreign authentication system. The access request is transparent to the user, allowing PingAccess to transparently manage access to systems using those foreign tokens. The request is also transparent to the protected application, which handles the access request as if it came from the user directly. Once token mediation has occurred, the token used for accessing the application is cached for continued use during the session.

The following illustration shows an example of token mediation using PingFederate to exchange a PA Token or OAuth Bearer Token for a different security token.

### Processing steps:

1. A user requests a Resource from PingAccess with a PA Token or OAuth Bearer Token.

**Info:** This example assumes the user has already obtained a PA Token or OAuth Bearer Token. See the *Session Management* scenario for information on how users authenticate with PingFederate and obtain a PA Token or OAuth Bearer Token.

2. PingAccess evaluates resource-level policies and performs token mediation by acquiring the appropriate security token from the PingFederate STS specified by the Site Authenticator.
3. PingAccess sends the request to the Site (Web application) with the appropriate token.
4. PingAccess returns the response to the client (not shown).

## What can I configure with PingAccess?

---

PingAccess includes a wide range of features that allow you to customize your identity access management deployment. To learn more about these features, read the following descriptions.

### Agents

Agents are web server plugins that are installed on the web server hosting the target application. Agents intercept client requests to protected applications and allow or deny the request to proceed by consulting the Policy Manager or using cached information. Agents communicate with the PingAccess Policy Server via the PingAccess Agent Protocol (PAAP) which defines in detail the possible interactions between agents and Policy Server. Agents have a name to identify them and a shared secret to authenticate with to Policy Server. Agents do not need to be unique. There can be any number of agents using the same name and secret and they are all treated equally by Policy Server. This is useful in complex deployments where unique agents would be difficult to manage. Agents can be assigned as the destination for one or more applications by name.

### Applications

Applications represent the protected web applications and APIs to which client requests are sent. Applications are composed of one or more resources and have a common Virtual Host and Context Root and correspond to a single target site. Applications also use a common Web Session and Identity Mapping. Access control and request processing rules can be applied to applications and their resources on the Policy Manager page to protect them. Applications can be protected by PingAccess Gateway or PingAccess Agent. In a gateway deployment, the target application is specified as a Site. In an agent deployment, the application destination is an Agent.

### Authentication requirements

Authentication Requirements are policies that dictate how a user must authenticate before access is granted to a protected Web Application. Authentication methods are string values and ordered in a list by preference. At runtime, the type of authentication attempted is determined by the order of the authentication methods.

For example, a user attempts to access a PingAccess Web Application configured with an authentication requirement list containing the values (password, cert). PingAccess redirects the user to PingFederate requesting either password or certificate user authentication. PingFederate authenticates the user based on the password and issues an OIDC ID Token to PingAccess (containing the authentication method that was used). PingAccess ensures that the authentication method matched the requirements and redirects the user to the originally requested Application with the PA cookie set. The user navigates to the Application and access is granted. When the user attempts to access a more sensitive Application, configured with an authentication requirement list containing the value (cert), they are redirected to PingFederate to authenticate with a certificate.

If you configure Applications with authentication requirement lists that have no overlap. For example, one list has (password), another list (cert), a user navigating between Applications may be required to authenticate each time they visit an Application. When configuring authentication requirement lists to protect higher value Applications with step-up authentication, consider including stronger forms of authentication when configuring lower value Applications.

### **Auth token management**

Auth token management settings define the issuer and signing configuration used by JWT identity mappings.

### **Availability profiles**

Availability Profiles are used in a Site configuration to define how PingAccess classifies a backend target server as failed. Sites require the selection of an availability profile, even if only one target is provided.

If multiple targets are specified in a site configuration but a load balancing strategy is not applied, then the Availability Profile will cause the first listed target in the site configuration to be used unless it fails. Secondary targets will only be used if the first target is not available.

### **Certificates**

Certificates are used to establish anchors used to define trust to certificates presented during secure HTTPS connections. Outbound secure HTTPS connections such as communication with PingFederate for OAuth access token validation, identity mediation, and communication with a target Site require a certificate trusted by PingAccess. If one does not exist, communication is not allowed.

Certificates used by PingAccess may be issued by a CA or self-signed. CA-issued certificates are recommended to simplify trust establishment and minimize routine certificate management operations. Implementations of an X.509-based PKI (PKIX) typically have a set of root CAs that are trusted, and the root certificates are used to establish chains of trust to certificates presented by a client or a server during communication.

The following formats for X.509 certificates are supported:

- Base64 encoded DER (PEM)
- Binary encoded DER

### **Clustering**

PingAccess can be configured in a clustered environment to provide higher scalability and availability for critical services.

PingAccess clusters are made up of three types of nodes:

<b>Administrative Node</b>	Provides the administrator with a configuration interface.
<b>Replica Administrative Node</b>	Provides the administrator with the ability to recover a failed administrative node using a manual failover procedure.
<b>Engine Node</b>	Handles incoming client requests and evaluates policy decisions based on the configuration replicated from the administrative node.

Any number of clustered engines can be configured in a cluster, but only one administrative console and one replica administrative console can be configured in a cluster.

Further use of subclusters provides better scaling of very large PingAccess deployments by allowing multiple engine nodes in the configuration to share certain information.

### HTTP requests

HTTP Requests are used to match a served resource with the originating client when one or more reverse proxies are between the client and the served resource. For example, when a reverse proxy sits between the client and the PingAccess server or a PingAccess agent, the additional proxy might be identified as the client. Such proxies can be configured to inject additional headers to relay the originating client address.

### Identity Mappings

Identity mappings make user attributes available to back-end sites that use them for authentication. There are multiple types of identity mappings, each with different behavior and a distinct set of fields to specify the identity mapping behavior.

### Key pairs

Key pairs are required for secure HTTPS communication. A Key Pair includes a private key and an X.509 certificate. The certificate includes a public key and the metadata about the owner of the private key.

PingAccess listens for client requests on the administrative console port and on the PingAccess engine port. To enable these ports for HTTPS, the first time you start up PingAccess, it generates and assigns a Key Pair for each port. These generated Key Pairs are assigned on the HTTPS Listeners page.

Additionally, Key Pairs are used by the **Mutual TLS Site Authenticator** to authenticate PingAccess to a target Site. When initiating communication, PingAccess presents the client certificate from a Key Pair to the Site during the mutual TLS transaction. The Site must be able to trust this certificate in order for authentication to succeed.

### Listeners

Listeners monitor ports for incoming requests. PingAccess can place listeners on ADMIN, ENGINE, and AGENT ports.

### Load balancing strategies

Load Balancing Strategies are used in a Site configuration to distribute the load between multiple backend target servers. Load balancing settings are optional, and only available if more than one target is listed for a site. This functionality can replace a load balancer appliance between the PingAccess engine nodes and the target servers, allowing for a simpler network architecture.

The Header-Based strategy requires a header be included in the request that defines the target to select from the Site configuration. This strategy has an option to fall back if the requested target is unavailable, or if the header is missing from the request.

The Round Robin strategy has a sticky session option that permits a browser session to be pinned to a persistent backend target. This strategy works in conjunction with the availability profile to select a target based on its availability, and the load balancer will not select a target that is in a failed state.

## **Policies**

The Policy Manager is a rich drag-and-drop interface where you can manage policies by creating Rules, building Rule Sets and Rule Set Groups, and applying them to Applications and Resources. Policies are rules, set of rules, or groups of rule sets applied to an application and its resources. Policies define how and when a client can access target Sites. When a client attempts to access an application resource identified in one of the policy's Rules, Rule Sets, or Rule Set Groups, PingAccess uses the information contained in the policy to decide whether the client can access the application resource and whether any additional actions need to take place prior to granting access. Rules can restrict access in a number of ways such as testing user attributes, time of day, request IP addresses, or OAuth access token scopes. Rules can also perform request processing such as modifying headers or rewriting URLs.

## **Proxies**

Configure settings to authenticate with a forward proxy server when PingAccess makes requests to sites or token providers.

## **Rules, Rule sets, and Rule set groups**

Rules are the building blocks for access control and request processing. There are many types of rules, each with different behavior and a distinct set of fields to specify the rule behavior. Rule Sets allow you to group multiple Rules into re-usable sets which can be applied to applications and resources. Rule set groups can contain rule sets or other rule set groups, allowing the creation of hierarchies of rules to any level of depth. Rule sets and rule set groups can be applied to applications and resources as required.

## **Sites**

Sites are the target applications or APIs which PingAccess Gateway is protecting and to which authorized client requests are ultimately forwarded to.

## **Site Authenticators**

When a client attempts to access a target Web Site, that Site may limit access to only authenticated clients. PingAccess integrates with those security models using Site Authenticators. PingAccess supports a variety of Site Authenticators that range from basic username/password authentication to certificate and token-based authentication. Create a Site Authenticator for the type of authentication the Site requires.

## **Token provider**

Token providers are used as a method of providing credentials for secure access to a given target.

## **Unknown resources**

Unknown resources are resources for which there is no PingAccess definition. You can specify the default and per-agent handling behavior for unknown resource requests and configure custom error responses.

## **Virtual Hosts**

Virtual Hosts enable PingAccess to protect multiple application domains and hosts. A Virtual Host is defined by the host name and host port.

## **Web sessions**

Web Sessions define the policy for Web application session creation, lifetime, timeouts, and their scope. Multiple Web Sessions may be configured to scope the session to meet the needs of a target set of applications. This improves the security model of the session by preventing unrelated applications from impersonating the end user.

# Installing PingAccess

---

## Install PingAccess

---

This document provides instructions to install PingAccess.

PingAccess can be installed on:

- [Linux](#)
- [Red Hat Enterprise Linux](#)
- [Windows](#)

After you install PingAccess, you:

- [Start PingAccess](#)
- [Access the admin console for the first time](#)
- [Change configuration database passwords](#) on page 73

You can also:

- [Stop PingAccess](#) on page 73
- [Run PingAccess as a service](#) on page 73
- [Uninstall PingAccess](#) on page 76

## Installation requirements

These sections detail system, hardware, and port requirements for installing PingAccess.

- [System requirements](#)
- [Hardware requirements](#)
- [Port requirements](#) on page 66

### System requirements

PingAccess is certified as compatible for deployment and configuration with systems meeting these requirements.

Ping Identity has qualified the following configurations and certified that they are compatible with the product. Variations of these platforms (for example, differences in operating system version or service pack) are supported up until the point at which an issue is suspected as being caused by the platform or other required software.

**Note:** PingAccess supports IPv4 addressing. There is currently no support for IPv6 addressing.

### Operating systems

**Note:** PingAccess has been tested with default configurations of operating system components. If your organization has customized implementations or has installed third-party plug-ins, deployment of the PingAccess server may be affected.

- Microsoft Windows Server 2012 R2 Datacenter
- Microsoft Windows Server 2016
- Red Hat Enterprise Linux ES 6.9
- Red Hat Enterprise Linux ES 7.5
- SUSE Linux Enterprise 11 SP4
- SUSE Linux Enterprise Server 12.3

**Docker support**

- Version: Docker 18.09.0 CE
- Host operating system: Canonical Ubuntu 16.04 LTS

**Virtual systems**

Although Ping Identity does not qualify or recommend any specific virtual-machine (VM) products, PingAccess has been shown to run well on several, including VMWare, Xen, and Windows Hyper-V.

**Info:** This list of products is provided for example purposes only. We view all products in this category equally. Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance and/or interoperability of any VM software with its products.

**Java runtime environment**

- Oracle Java SE Runtime Environment (Server JRE) 8 (64-bit)
- Oracle Java SE Development Kit (JDK) 11 (64-bit)
- OpenJDK 11 (64-bit)
- Amazon Coretto 8 (64-bit)
- Amazon Coretto 11 (64-bit)

**PingFederate**

- PingFederate 8.4
- PingFederate 9.2

**Browsers for end users**

- Chrome
- Firefox
- Safari
- Edge
- Internet Explorer 9 and higher
- Android
- iOS

**Browsers for admin console**

- Chrome
- Firefox
- Internet Explorer 11 and higher

**Audit event storage (external database)**

- Oracle 11g R2
- Oracle 12c
- MS SQL Server 2012
- MS SQL Server 2016
- PostgreSQL 9.6.1

**Hardware requirements**

PingAccess is supported on hardware that meets these requirements.

**Info:** Although it is possible to run PingAccess on less powerful hardware, the following guidelines accommodate disk space for default logging and auditing profiles and CPU resources for a moderate level of concurrent request processing.

Although the requirements for different environments will vary, we recommend running PingAccess on hardware that meets or exceeds these specifications:

- Multi-CPU/Cores (8 or more)
- 4 GB of RAM
- 2.1 GB of available hard drive space

### Port requirements

This table summarizes the ports and protocols that PingAccess uses to communicate with external components. This information provides guidance for firewall administrators to ensure the correct ports are available across network segments.

**Info:** *Direction* refers to the direction of requests relative to PingAccess. *Inbound* requests are requests received by PingAccess from external components. *Outbound* requests are requests sent by PingAccess to external components.

Service	Port details	Source	Description
PingAccess Administrative Console	Protocol: HTTPS Transport: TCP Default port: 9000 Destination: PingAccess Administrative Engine Direction: Inbound	PingAccess Administrator browser, PingAccess administrative API REST calls, PingAccess Replica Admin and clustered Engine nodes	Used for incoming requests to the PingAccess administrative console. Configurable using the <code>admin.port</code> property in the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information. This port is also used by clustered engine nodes and the replica admin node to pull configuration data using the admin REST API.
PingAccess Cluster Communications Port	Protocol: HTTPS Transport: TCP Default port: 9090 Destination: PingAccess Administrative Engine Direction: Inbound	PingAccess Administrator browser, PingAccess administrative API REST calls, PingAccess Replica Admin and clustered Engine nodes	Used for incoming requests where the clustered engines request their configuration data. Configurable using the <code>clusterconfig.port</code> property in the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information. This port is also used by clustered engine nodes and the replica admin node to pull configuration data using the admin REST API.

Service	Port details	Source	Description
PingAccess Engine	Protocol: HTTP/HTTPS Transport: TCP Default port: 3000* Destination: PingAccess Engine Direction: Inbound	Client Browser, Mobile Devices, PingFederate Engine	Used for incoming requests to the PingAccess runtime engine. Configurable using the <code>Listeners</code> configuration page. See the <a href="#">PingAccess user interface reference guide</a> for more information.
PingAccess Agent	Protocol: HTTP/HTTPS Transport: TCP Default port: 3030 Destination: PingAccess Engine Direction: Inbound	PingAccess Agent	Used for incoming Agent requests to the PingAccess runtime engine. Configurable using the <code>agent.http.port</code> property of the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information.
PingFederate Traffic	Protocol: HTTPS Transport: TCP Default port: 9031 Destination: PingFederate Direction: Outbound	PingAccess Engine	Used to validate OAuth Access Tokens, ID Tokens, make STS calls for Identity Mediation, and return authorized information about a user. Configurable using the <code>PingFederate Settings</code> page within PingAccess. See the <a href="#">PingAccess user interface reference guide</a> for more information.
PingAccess Cluster Traffic	Protocol: JGroups Transport: TCP Default port: 7610 Destination: PingAccess Engine Direction: Inbound	PingAccess Engine	Used for communications between engine nodes in a cluster. Configurable using the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information.
PingAccess Cluster Traffic	Protocol: JGroups Transport: TCP Default port: 7710 Destination: PingAccess Engine Direction: Inbound	PingAccess Engine	Used by other nodes in the cluster as part of the cluster's failure-detection mechanism. Configurable using the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information.

Service	Port details	Source	Description
PingAccess Cluster Traffic	Protocol: JGroups Transport: UDP Default port: 7500 Destination: PingAccess Engine Direction: Inbound	PingAccess Engine	Used by other nodes in the same cluster to share information. Configurable using the <code>run.properties</code> file. See the <a href="#">Configuration file reference guide</a> for more information.

\*In addition to port 3000, additional engine listener ports defined in the configuration need to be open as well.

## Install PingAccess on Linux

You can install PingAccess on a SUSE Linux system.

### Before you begin

Prior to starting the installation, the following prerequisites must be satisfied:

- Ensure the [installation requirements](#) are met.
- Ensure you are logged on to your system with appropriate privileges to install and run an application.

**Note:** On Linux, we recommend that you install and run PingAccess as a non-root user.

- A supported Java runtime must be installed:
  - Oracle Server JRE (Java SE Runtime Environment) 8u192: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - Oracle Java SE Development Kit 11.0.1: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - OpenJDK 11.0.1: <http://jdk.java.net/11/>
- The System or User Environment Variable `JAVA_HOME` must exist and be set to a value that represents the location of your Java installation (ie; `usr/java/jdk 1.8.0_74`).
- The JRE `/bin` directory (ie; `usr/lib64/jvm/jre/bin`) path must be added to the `PATH` variable so it is available for scripts that depend on it.
- You must have a `pingaccess.lic` license file.

**Note:** If you do not have one, you can request an evaluation key at the [Request a License Key page](http://www.pingidentity.com/content/pic/en/products/request-license-key.html) ([www.pingidentity.com/content/pic/en/products/request-license-key.html](http://www.pingidentity.com/content/pic/en/products/request-license-key.html)). During the first run of PingAccess, you will be prompted to upload the license file via the UI.

### Steps

1. Download the distribution ZIP file.
2. Extract the distribution ZIP file into your installation directory.

### Results

**Tip:** If you are deploying PingAccess in a cluster configuration, see PingAccess cluster configuration documentation.

## Install PingAccess on Red Hat Enterprise Linux

You can install PingAccess on a Red Hat Enterprise Linux system.

## Before you begin

Prior to starting the installation, the following prerequisites must be satisfied:

- Ensure the [installation requirements](#) are met.
- Ensure you are logged on to your system with appropriate privileges to install and run an application.

**Note:** On RHEL, we recommend that you install and run PingAccess as a non-root user.

- A supported Java runtime must be installed:
  - Oracle Server JRE (Java SE Runtime Environment) 8u192: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - Oracle Java SE Development Kit 11.0.1: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - OpenJDK 11.0.1: <http://jdk.java.net/11/>
- The System or User Environment Variable JAVA\_HOME must exist and be set to a value that represents the location of your Java installation (ie; `usr/java/jdk 1.8.0_74`).
- The JRE `/bin` directory (ie; `usr/lib64/jvm/jre/bin`) path must be added to the `PATH` variable so it is available for scripts that depend on it.
- You must have a `pingaccess.lic` license file.

**Note:** If you do not have one, you can request an evaluation key at the [Request a License Key page](http://www.pingidentity.com/content/pic/en/products/request-license-key.html) ([www.pingidentity.com/content/pic/en/products/request-license-key.html](http://www.pingidentity.com/content/pic/en/products/request-license-key.html)). During the first run of PingAccess, you will be prompted to upload the license file via the UI.

## Steps

1. Download the installation script.
2. Optional: Download the distribution tar file into your installation directory.

**Note:** Downloading the distribution file before running the script may save time. If you do not download the distribution file, the installer downloads the required files during the installation process.

3. Launch the installation script: `sudo -E ./pa-install-<version>.sh`

**Note:** On supported RHEL versions, the newer **systemd** scripting service is used during installation. On earlier versions, the installation is performed using the older **systemv** scripting service.

4. Follow the prompts on the screen, enter your preferred options, or accept the default values. The installation completes by starting up PingAccess according to the parameter values you supplied. Wait until you see the "Starting" and "Started" messages.
5. Open a browser and enter the machine and PingAccess admin port in the URL, for example:
 

```
https://yourhost:9000
```
6. Finalize your setup.

## Results

**Tip:** If you are deploying PingAccess in a cluster configuration, see PingAccess cluster configuration documentation.

## Install PingAccess on Windows

You can install PingAccess on a Windows system.

### Before you begin

Prior to starting the installation, the following prerequisites must be satisfied:

- Ensure the [installation requirements](#) are met.
- Ensure that you are logged on to your system with appropriate privileges to install and run an application.

**Note:** The Windows installer will ask for admin privileges during installation.

- A supported Java runtime must be installed:
  - Oracle Server JRE (Java SE Runtime Environment) 8u192: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - Oracle Java SE Development Kit 11.0.1: <http://www.oracle.com/technetwork/java/javase/downloads/index.html>
  - OpenJDK 11.0.1: <http://jdk.java.net/11/>
- The System Environment Variable JAVA\_HOME must exist and be set to a value that represents the location of your Java installation (ie; C:\Program Files\Java\jre 1.8.0\_91).
- The *javapath* directory path (ie; C:\Program Files\Oracle\Java\javapath) must be added to the PATH variable.

## Steps

1. Download the PingAccess Windows installer.
2. Double-click on the icon to launch the PingAccess Setup Wizard.
3. Click **Next** and follow the prompts to complete the installation using the following information for the **Operational Mode** that you select.

Operational Mode	Requirements
Standalone	<p><b>Ports</b></p> <ul style="list-style-type: none"> <li>• <b>PingAccess administrative console:</b> TCP 9000</li> <li>• <b>PingAccess agent protocol:</b> TCP 3030</li> </ul>
Clustered Admin Node	<p><b>Ports</b></p> <ul style="list-style-type: none"> <li>• <b>PingAccess administrative console:</b> TCP 9000</li> <li>• <b>Configuration query port:</b> TCP 9090</li> </ul>
Clustered Replica Admin Node	<p><b>Ports</b></p> <ul style="list-style-type: none"> <li>• <b>PingAccess administrative console:</b> TCP 9000</li> <li>• <b>Configuration query port:</b> TCP 9090</li> </ul> <p><b>Prerequisites</b></p> <ul style="list-style-type: none"> <li>• A Clustered Admin Node must be installed and configured.</li> <li>• A configuration data archive file for the Replica Admin Node must be available. Consult PingAccess clustering documentation for more information.</li> </ul> <p><b>Note:</b> We recommend that you install the Clustered Replica Admin Node on a separate machine in the same network.</p>
Clustered Engine Node	<p><b>Ports</b></p> <ul style="list-style-type: none"> <li>• <b>PingAccess agent protocol:</b> TCP 3030</li> </ul> <p><b>Prerequisites</b></p> <ul style="list-style-type: none"> <li>• A Clustered Admin Node must be installed and configured.</li> <li>• A configuration data archive file for the Clustered Engine Node must be available. Consult PingAccess clustering documentation for more information.</li> </ul>

4. Copy the URL of the PingAccess admin console that is displayed on the final screen of the PingAccess setup wizard, then click **Finish**.
5. To customize and finalize the PingAccess setup, paste the URL you copied into your web browser and connect to the admin console of the instance you have just installed.

## Start PingAccess

---

After you have installed PingAccess, you start the service so that you can complete your configuration.

### About this task

**Note:** If you installed PingAccess using the Windows installer, the service is installed and started automatically.

### Steps

1. In a command prompt or terminal window, change to the PingAccess `bin` directory:
  - On Linux: `cd PA_HOME/bin`
  - On Windows: `cd PA_HOME\bin`
2. Start the `run` script for the platform:
  - On Linux: `./run.sh`
  - On Windows: `run.bat`

### Results

Wait for the script to execute. PingAccess is started when you see the message “PingAccess running...” in the command window.

## Access the admin console for the first time

---

After you have installed and started PingAccess, you can access the admin console and perform configuration and first-time logon tasks.

### Steps

1. Launch your browser and go to: `https://<DNS_NAME>:9000`  
<DNS\_NAME> is the fully-qualified name of the machine running PingAccess.  
**Info:** If you have not yet installed a PingAccess license, the server will redirect you to the **License Upload** screen outside of the main UI. See the [PingAccess User Interface Reference Guide](#) for more information.
2. Sign in with the default username and password:  
**Username:** Administrator  
**Password:** 2Access
3. Read and accept the license agreement.
4. Change the default administrator password on the **First Time Login** page, then click **Continue**.  
**Info:** The new password must conform to the rules specified by the `pa.admin.user.password.regex` property in `run.properties`.  
The PingAccess administrative console appears.

## Results

Upon a successful login, PingAccess creates a backup of the current configuration to allow the administrator to revert any changes made. This backup is stored in `PA_HOME/data/archive`. The number of backup files can be controlled using the `pa.backup.filesToKeep` property in `run.properties`.

**CAUTION:** As the backup file contains your complete PingAccess configuration, ensure the file is protected with appropriate security controls in place.

## Access the PingAccess administrative API

---

You can access the PingAccess administrative API.

### Steps

Send HTTP request to URL `https://<host>:<admin-port>/pa-admin-api/v3/<api-endpoint>`.

**Note:** You must provide appropriate administrator credentials in the request.

#### Example

For example, the following cURL command will return a list of all defined applications by sending a Get request to the applications resource:

```
curl -k -u Administrator:Password1 -H "X-Xsrf-Header: PingAccess" https://localhost:9000/pa-admin-api/v3/applications
```

- The `-u Administrator:Password1` parameter sends Basic Authentication header with the username `Administrator` and password `Password1`
- The `-k` parameter specifies to ignore HTTPS certificate issues
- The `-H "X-Xsrf-Header: PingAccess"` parameter sends an X-XSRF-Header with value `PingAccess`

## Access the interactive administrative API documentation

You can view interactive documentation for the administrative API endpoints.

### Steps

1. Launch your browser and go to URL `https://<host>:<admin-port>/pa-admin-api/v3/api-docs/`. For example, `https://localhost:9000/pa-admin-api/v3/api-docs/`.
2. The browser may prompt for credentials. Enter the administrator username and password.
3. Use the administrative API to perform a variety of administrative tasks, including those to gather information as seen in the following example that uses the interactive Administrative API documentation to see all defined applications:
  - a) Click on the `/applications` endpoint to expand it.
  - b) Click on the GET method (`GET /applications`) to expand it.
  - c) Enter parameters values or leave all blank.
  - d) Click **Try It Out**.
  - e) The Request URL, Response Body, Response Code, and Response Headers appear.

## Change configuration database passwords

---

You can change the file and user passwords for the PingAccess configuration database.

### About this task

The PingAccess configuration database is protected by two passwords - a file password and a user password. These passwords both default to `2Access`, but should be changed for production environments.

Changing either password requires PingAccess be shut down.

### Steps

1. Open a terminal window and change to the `<PA_HOME>/bin` directory.
2. Ensure that the `JAVA_HOME` environment variable is set correctly by executing the command `echo $JAVA_HOME`.
3. Ensure that the proper Oracle Java executable is in your path. Enter the command `java -version`. If this command returns a value indicating that the Java executable is not a supported version of Oracle Java, correct this issue before continuing.
4. Shut down PingAccess.
5. Optional: To change the database file password:
  - a) If you are using Windows, run this command and note the output: `dbfilepasswd.bat old_password new_password`
  - b) If you are using Linux, run this command and note the output: `./dbfilepasswd.sh old_password new_password`
  - c) On all operating systems, update the `pa.jdbc.filepassword` property in `PA_HOME/conf/run.properties` with the obfuscated password output from the command given above.
6. Optional: To change the database user password:
  - a) If you are using Windows, run this command and note the output: `dbuserpasswd.bat file_password old_password new_password`
  - b) If you are using Linux, run this command and note the output: `./dbuserpasswd.sh file_password old_password new_password`
  - c) On all operating systems, update the `pa.jdbc.password` property in `PA_HOME/conf/run.properties` with the obfuscated password output from the command given above.
7. Restart PingAccess.

## Stop PingAccess

---

You can stop PingAccess as a prerequisite for some maintenance or uninstallation tasks.

### Steps

1. Press `Ctrl+C` in the command-prompt or terminal window.
2. If PingAccess is running on Windows, press `y` when prompted to terminate the script.

## Run PingAccess as a service

---

PingAccess can run as a service on Linux and Windows 64-bit operating systems, enabling PingAccess to start automatically when the operating system is started.

The service runs as the `root` (Linux) and `System` (Windows) user by default.

The following tasks allow you to manage PingAccess as a service:

- [Configure PingAccess to run as a Linux systemd service](#) on page 74
- [Configure PingAccess to run as a Linux systemv service](#) on page 75
- [Configure Multiple Instances of PingAccess as Linux services](#) on page 75
- [Remove the PingAccess Linux service](#) on page 75
- [Configure PingAccess to run as a Windows service](#) on page 76
- [Remove the PingAccess Windows service](#) on page 76

**Tip:** Before performing the following procedures, ensure that PingAccess runs normally by manually starting the server. See [Run PingAccess for the First Time](#) for more information.

## Configure PingAccess to run as a Linux systemv service

You can configure PingAccess to run as a Linux systemv service, causing it to start automatically when Linux starts.

### About this task

**Note:** The service script will only start if JAVA\_HOME and PA\_HOME are set and the PingAccess license file is found.

### Steps

1. Copy the PingAccess script file from `PA_HOME/sbin/linux/pingaccess` to `/etc/init.d`.
2. Optional: Create a new user to run PingAccess.
3. Create the folder `/var/run/pingaccess` and ensure that the user who will run the service has read and write permission to the folder.
4. Edit the script file `/etc/init.d/pingaccess` and set the values of following variables at the beginning of the script:
  - `export JAVA_HOME=` specify the Java install folder
  - `export PA_HOME=` specify the PingAccess install folder
  - `export USER=` (optional) specify user name to run the service, or leave empty for default
5. Register the service by running the command `chkconfig --add pingaccess` from the `/etc/init.d` folder.
6. Make the service script executable by running the command `chmod +x pingaccess`.

### Results

Once registered, you can use the `service` command to control the pingaccess service. The available commands are:

<b>start</b>	Start the PingAccess Service
<b>stop</b>	Stop the PingAccess Service
<b>restart</b>	Restart the PingAccess Service
<b>status</b>	Show the status of the PingAccess service and the service PID

#### Example

The command `service pingaccess status` displays the current status of the running PingAccess service.

## Configure PingAccess to run as a Linux systemd service

You can configure PingAccess to run as a Linux systemd service, causing it to start automatically when Linux starts.

### About this task

**Note:** The service script will only start if JAVA\_HOME and PA\_HOME are set and the PingAccess license file is found.

### Steps

1. Copy the configuration file from `PA_HOME/sbin/linux/pingaccess.service` to `/etc/systemd/system/pingaccess.service`.
2. In the `pingaccess.service` file, replace the following variables:
  - PA\_HOME
  - PA\_USER
  - JAVA\_HOME
3. Allow read/write activity on the service using the command `chmod 644 /etc/systemd/system/pingaccess.service`.
4. Load the systemd service using the command `systemctl daemon-reload`.
5. Enable the service using the command `systemctl enable pingaccess.service`.
6. Start the service using the command `systemctl start pingaccess.service`.

## Configure Multiple Instances of PingAccess as Linux services

You can configure multiple instances of PingAccess on a single host as Linux services.

### About this task

For hosts running multiple instances of PingAccess that need to be started as a service, follow the procedure used for [Configuring PingAccess as a Linux Service](#), but make the following modifications to the script for each service:

### Steps

- Use a unique script name for each instance
- Use a separate directory structure for each instance in the filesystem
- Configure the following settings in the script file for each instance:
  - APPNAME: A unique value for each instance
  - PA\_HOME: The path to the PingAccess instance
  - JAVA\_HOME: The path to the Java installation folder
  - USER: Optional value for the user name used to run the service

## Remove the PingAccess Linux service

You can remove the PingAccess service from a Linux system.

### About this task

**Note:** The following commands must be run as the `root` user.

### Steps

1. Stop the service by running `/etc/init.d/pingaccess stop`.
2. Run `chkconfig --delete pingaccess`.

3. Optional: Delete the `/etc/init.d/pingaccess` script.

## Configure PingAccess to run as a Windows service

You can configure PingAccess to run as a Windows service, causing it to start automatically when Windows starts.

### About this task

**Info:** Before performing this procedure, ensure that PingAccess runs normally by manually starting the server (see [Run PingAccess for the First Time](#)).

**Note:** If you installed PingAccess using the Windows installer, the service is installed and started automatically.

### Steps

1. [Install PingAccess](#).
2. Ensure you are logged in with full Administrator privileges.
3. Start a command prompt as an Administrator.
4. In the command prompt, change to the `PA_HOME\sbin\windows` directory and run the `install-service.bat` script.
5. Open the Windows **Control Panel > Administrative Tools > Services**.
6. Right-click **PingAccess Service** from the list of available services and select **Start**.  
The service starts immediately and restarts automatically on reboot. (You can change the default **Start type** setting in the **Properties** dialog.)

## Remove the PingAccess Windows service

You can remove the PingAccess service from a Windows system.

### About this task

To remove the PingAccess Windows Service, perform the following steps as an Administrator:

### Steps

1. Open a command prompt.
2. Change the current directory to `PA_HOME\sbin\windows`.
3. Run `uninstall-service.bat`.
4. When the script has finished, remove the `PA_HOME` environment variable from the system.

## Uninstall PingAccess

---

You can uninstall PingAccess.

### Steps

1. [Stop PingAccess](#) on page 73.
2. Delete the PingAccess installation directory.

# Configuring and Customizing PingAccess

---

## Configure session management

---

### Configure session management

This document provides information regarding session management using PingAccess. Use this document to learn about the concepts involved and to configure PingAccess for server-side session management using PingFederate.

#### Web Sessions

Web Sessions define the policy for Web application session creation, lifetime, timeouts, and their scope. Multiple Web Sessions may be configured to scope the session to meet the needs of a target set of applications. This improves the security model of the session by preventing unrelated applications from impersonating the end user. Use the following tasks to configure secure Web Sessions for use with specific applications and to configure global Web Session settings.

#### Application scoped Web Sessions

PingAccess Tokens can be configured to have their Web Sessions scoped to a specific application. This improves the security model of the session by preventing unrelated applications from impersonating the end user.

Several controls exist to scope the PA Token to an application:

##### Audience Attribute

The audience attribute defines who the token is applicable to and is represented as a short, unique identifier. Requests are rejected that contain a PA Token with an audience that differs from what is configured in the Web Session associated with the target Resource.

##### Audience Suffix

The audience attribute is also used as a suffix of the cookie name to ensure uniqueness. For example, PA.businessAppAudience.

##### Cookie Domain

The cookie domain can also optionally be set to limit where the PA Token is sent.

**Info:** In addition to these controls, parameters such as session timeout can be adjusted to match the policy requirements of each application.

Corresponding OAuth clients must be defined in PingFederate for each Web Session. Redirect URL whitelists defined in PingFederate dictate from which servers and domains the session can originate. Controlling this within PingFederate enables flexibility of the attribute contract (and its fulfillment) for that particular application. This ensures that each application and its associated policies only deal with attributes related to it.

### Configure server-side session management

You can implement server-side session management in one of two ways.

- PingAccess can reject a PingAccess cookie associated with a PingFederate session that has been invalidated as a result of an end-user driven logout.
- The end user can initiate a logout from all PingAccess issued web sessions using a centralized logout.

The first of these scenarios provides increased scalability and security, ensuring the PingFederate session is terminated and that subsequent session validation requests are rejected. This scenario implies a user logout from PingAccess protected resources through the invalidation of the related PingFederate session.

The second scenario provides improved performance and end user experience. When the user explicitly logs out of the PingAccess issued session, all related PingAccess cookies are deleted, ensuring the client is no longer authenticated to resources protected by PingAccess. In this scenario, the user has explicitly logged out from all of those protected services.

PingAccess needs to be configured only for the first of these two scenarios. These options are not mutually exclusive, and can be combined to provide comprehensive session management at the server.

### Configure PingFederate for session management

You can configure PingFederate to be able to revoke PingAccess session cookies.

#### Steps

1. Log in to the PingFederate Administrative Console
2. Navigate to **Server Configuration > Server Settings > Roles & Protocols**
3. Ensure that **Enable OAuth 2.0 Authorization Server (AS) role** and **OpenID Connect** are enabled. Create or modify an existing client.
4. From the main administration page, navigate to **OAuth Settings > Authorization Server Settings** and configure the authorization server settings.
5. Return to the main administration page, then go to **OAuth Settings > Client Management**
6. Create or modify an existing client.
7. Ensure that **Client Secret** is enabled, then enter a client secret to be used by PingAccess for authentication.
8. In the OpenID Connect section of the client's configuration page, enable **Grant Access to Session Revocation API**.

**Note:** This setting is the main setting that enables the server-side session management feature in PingFederate.

9. Click **Save** to save your changes.

### Configure PingFederate for user-initiated single logout

You can configure PingFederate to provide PingAccess with access to the PingFederate-managed session.

#### Steps

1. Log in to the PingFederate administrative console.
2. Navigate to **OAuth Settings > Authorization Server Settings**.
3. Select **Track User Sessions for Logout** under **OpenID Connect Settings**.
4. Click **Save**.
5. Navigate to **OAuth Settings > OpenID Connect Policy Management** and click an existing policy.
6. Click **Manage Policy**, then enable **Include Session Identifier in ID Token**.  
For more information about configuring an OpenID Connect Policy, see [Configuring OpenID Connect Policies](#) in the *PingFederate Administrator's Manual*.
7. Click **Save**.
8. Navigate to **OAuth Settings > Client Management** and select the client to be used by PingAccess.
9. In the OpenID Connect section of the client's configuration page, enable **PingAccess Logout Capable**.

**Tip:** If this option is not available, ensure that the **Track User Sessions for Logout** setting change made in step 3 was saved.

10. Click **Save**.

### Configure PingAccess for server-side session management

You can configure PingAccess to enable server-side session management.

#### Steps

1. Log in to the PingAccess administrative console.
2. Click **Settings > Access > Web Sessions**.
3. Either [create a new web session](#) or [edit an existing web session](#).
4. In the **Client ID** field, enter the Client ID defined in PingFederate.
5. Enter the client secret associated with the specified Client ID.
6. Click the **Advanced** tab.
7. Select **Validate Session** to enable the server-side session management feature.
8. Click **Save**.

## Configure logging

---

### Configure logging

This document describes the types of logging performed by PingAccess and provides instructions for configuring PingAccess logging.

### Security audit logging

The PingAccess audit logs record a selected subset of transaction log information at runtime plus additional details, intended to facilitate security auditing and regulatory compliance.

The logs are located in `PA_HOME/log/`. Elements recorded in these logs are described in the table below, and are configured in `conf/log4j2.xml`.

**Important:** Log files can be viewed or modified using a variety of common applications. As such, it is possible for log files to be manipulated to include untrusted or malicious data. Administrators should take appropriate steps to secure these files. Furthermore, these files should not be opened in applications that could allow for data execution, such as internet browsers or Microsoft Office products. It is highly recommended that administrators open these files in a common, lightweight text editor.

PingAccess generates these audit logs:

<code>pingaccess_engine_audit.log</code>	Records transactions of configured Resources. Additionally, the log records transaction details when PingAccess sends requests to PingFederate (for example, STS, OAuth2, JWS).
<code>pingaccess_api_audit.log</code>	Records PingAccess administrative API transactions. These transactions represent activity in the PingAccess administrative console. This log also records transaction activity if you are using scripts to configure PingAccess.
<code>pingaccess_agent_audit.log</code>	Records transactions between PingAccess Agents and the PingAccess Engine.

### Audit log configuration

Item	Description
<code>%d</code>	Transaction time.

Item	Description
exchangeId	Identifies the ID for a specific request/response pair.
AUDIT.applicationID	Specifies the ID of the requested application.
AUDIT.applicationName	Specifies the name of the requested application.
AUDIT.resourceID	Specifies the ID of the requested resource.
AUDIT.resourceName	Specifies the name of the requested resource.
AUDIT.pathPrefix	Specifies the path prefix of the requested application or resource.
AUDIT.pathPrefixType	Indicates the pattern type of the path prefix, Wildcard or Regex.
AUDIT.authMech	Mechanism used for authentication. Engine Auditing - Cookie (WAM session), OAuth, unknown (for example, pass-through or static assets). Pass-through assets are Resources with no policies or Web session configured. Admin Auditing - Basic, OAuth, Cookie, unknown ( unknown displays only in an authentication failure).
AUDIT.client	IP address of the requesting client.
AUDIT.failedRuleName	Name of the Rule that failed. If no Rule failure occurred, this field is blank. This element is applicable only to the pingaccess_engine_audit.log.
AUDIT.failedRuleType	Type of Rule that failed. If no Rule failure occurred, this field is blank. This element is applicable only to the pingaccess_engine_audit.log.
AUDIT.failedRuleClass	The Java class of Rule that failed. If no Rule failure occurred, this field is blank. This element is applicable only to the pingaccess_engine_audit.log.
AUDIT.failedRuleSetName	Name of the containing Rule Set that failed. If no Rule failure occurred, this field is blank. This element is applicable only to the pingaccess_engine_audit.log.
AUDIT.host	PingAccess host name or IP address.
AUDIT.targetHost	Backend target that processed the request and generated a response to the PingAccess engine.
AUDIT.method	HTTP method of the request. For example, GET.
AUDIT.resource	Name of the Resource used to fulfill the request. This element is applicable only to the pingaccess_engine_audit.log.
AUDIT.responseCode	HTTP status code of the response. For example, 200.
AUDIT.requestUri	Request URI portion of the request (for example, /foo/bar).
AUDIT.subject	Subject of the transaction.

Item	Description
AUDIT.trackingId	<p>The PingFederate Tracking ID. This element can be used to help correlate audit information in the PingAccess audit log with information recorded in the PingFederate audit log.</p> <p>The value of this depends on whether the application type is <code>Web</code> or <code>API</code>.</p> <p>If the application type is <code>Web</code>, the value is presented as <code>tid:&lt;Session_Identifier&gt;</code>. The <code>&lt;Session_Identifier&gt;</code> can be used by the <a href="#">PingFederate Session Revocation API</a> to revoke the session without disabling the user in the identity store.</p> <p>If the application type is <code>API</code>, the value is presented as <code>atid:&lt;Hash&gt;</code>. The <code>&lt;Hash&gt;</code> value is derived from the OAuth Access token for the session, and only serves as an identifier; it cannot be used for session revocation.</p>
AUDIT.reqReceivedMillisec	Time in milliseconds (since 1970) that a client request was first received
AUDIT.reqSentMillisec	Time in milliseconds (since 1970) that the agent or engine sent a backchannel or proxy request
AUDIT.respReceivedMillisec	Time in milliseconds (since 1970) that the agent or engine received a response from a backchannel call or proxy request
AUDIT.respSentMillisec	Time in milliseconds (since 1970) that a response was sent back to the client
AUDIT.roundTripMS	The <code>respSentMillisec</code> time minus the <code>reqReceivedMillisec</code> time. This represents the total number of milliseconds it took PingAccess to respond to a client's request (including the <code>proxyRoundTripMS</code> ).
AUDIT.proxyRoundTripMS	The <code>respReceivedMillisec</code> time minus the <code>reqSentMillisec</code> time. This represents the total number of milliseconds PingAccess was waiting for another entity to respond to a backchannel call or proxy request.
AUDIT.userInfoReqSentMillisec	The time in milliseconds (since 1970) that the engine sent a request to the token provider's OIDC <code>UserInfo</code> endpoint.
AUDIT.userInfoRespReceivedMillisec	The time in milliseconds (since 1970) that the engine received a response from the token provider's OIDC <code>UserInfo</code> endpoint.
AUDIT.userInfoRoundTripMS	The <code>userInfoRespReceivedMillisec</code> minus the <code>userInfoReqSentMillisec</code> time. This represents the total number of milliseconds it took PingAccess to receive a response from the token provider's <code>UserInfo</code> endpoint.

Item	Description
<code>appRequestHeader {a-header-name}</code>	HTTP request header value for the given HTTP request header name. Represents the header value that PingAccess sends to the back end site.
<code>appResponseHeader {a-header-name}</code>	HTTP response header value for the given HTTP request header name. Represents the header value received from the application.
<code>clientRequestHeader {a-header-name}</code>	HTTP request header value for the given HTTP request header name. Represents the header value received from the client.
<code>clientResponseHeader {a-header-name}</code>	HTTP response header value for the given HTTP request header name. Represents the header value returned to the client.

## Logging

PingAccess logging is handled by the log4j2 asynchronous logging library, configured using `conf/log4j2.xml`.

**Info:** Audit logs are also configurable in `conf/log4j2.xml`. These logs record a selected subset of transaction log information at runtime plus additional details (see [Security Audit Logging](#)).

By default, logging information is output to `PA_HOME/logs/pingaccess.log`, and file logging uses the *rolling* file appender. PingAccess keeps a maximum of 10 log files, each with a maximum size of 100 MB. Once 10 files accumulate, PingAccess deletes the oldest. These defaults can be changed by locating and modifying the following properties in the `<Appenders>` section of `log4j2.xml`:

- Changing the log file name:

```
<RollingFile name="File"
  fileName="${sys:pa.home}/log/pingaccess.log"
  filePattern="${sys:pa.home}/log/pingaccess.log.%i"
  ignoreExceptions="false">
```

- Setting the maximum log size:

```
<SizeBasedTriggeringPolicy size="100000 KB"/>
```

- Setting the maximum number of log files:

```
<DefaultRolloverStrategy max="10"/>
```

In addition to the standard log4j2 items, PingAccess adds the following custom item that can be used in the `log4j2.xml` `<PatternLayout>` configuration:

Item	Description
<code>exchangeId</code>	Identifies the ID for a specific request/response pair.

For example, the following line from `log4j2.xml` incorporates the `exchangeId` in the output:

```
<pattern>%d{ISO8601} %5p [%X{exchangeId}] %c:%L - %m%n</pattern>
```

**Note:** The `%X` conversion character is required for the `exchangeId` to be displayed properly.

## Configure log levels

You can define log levels for specific package or class names in order to get more (or less) logging from a class or group of classes.

### About this task

If the log level is not specified for a particular package or class, the settings for the root logger are inherited.

### Steps

1. Open `conf/log4j2.xml` in an editor.
2. Locate the `<AsyncLogger>` element for the package or class you wish to adjust the logging level for.

```
<AsyncLogger name="com.pingidentity" level="DEBUG" additivity="false"
  includeLocation="false">
```

3. Modify the `level` attribute to set the desired log level.  
Valid values are OFF, FATAL, ERROR, WARN, INFO, DEBUG, and TRACE.
4. Save the modified file. PingAccess will automatically make the changes effective within 30 seconds.

## Configure a class or package log level

You can use the `log4j2.xml` file to configure the log level for a class or package.

### Steps

1. Open `conf/log4j2.xml` in an editor. Class or package loggers are defined in the `<AsyncLogger>` `name` attribute. For example, cookie logging is enabled using the line:

```
<AsyncLogger name="com.pingidentity.pa.core.interceptor.CookieLoggingInterceptor"
  level="TRACE" additivity="false" includeLocation="false">
  <AppenderRef ref="File"/>
</AsyncLogger>
```

2. Set the `level` value in the `<AsyncLogger>` element to one of the following values:

OFF, FATAL, ERROR, WARN, INFO, DEBUG, TRACE.

For example, to apply TRACE level logging for the `com.pingidentity` package, locate the following line:

```
<AsyncLogger name="com.pingidentity" level="DEBUG" additivity="false"
  includeLocation="false">
```

and change it to:

```
<AsyncLogger name="com.pingidentity" level="TRACE" additivity="false"
  includeLocation="false">
```

3. Save the file.

## Enable cookie logging

Cookie logging is an optional feature in the TRACE log level.

## Steps

1. Edit `conf/log4j2.xml` and uncomment the following section:

```
<AsyncLogger
  name="com.pingidentity.pa.core.interceptor.CookieLoggingInterceptor"
  level="TRACE" additivity="false" includeLocation="false">
  <AppenderRef ref="File"/>
</AsyncLogger>
```

2. Save the file.

## Append log messages to syslog and the console

You can enable additional output destinations (called *appenders*).

### About this task

Console and syslog appenders are pre-configured in `log4j2.xml`, but are disabled by default.

To enable additional appenders, perform the following steps:

## Steps

1. Open `conf/log4j2.xml` in an editor.
2. Locate the following lines in the `<Loggers>` element:

```
<AsyncLogger name="com.pingidentity" level="DEBUG" additivity="false"
  includeLocation="false">
  <AppenderRef ref="File"/>
  <!--<AppenderRef ref="CONSOLE" />-->
  <!--<AppenderRef ref="SYSLOG" />-->
</AsyncLogger>
```

**Note:** If you have customized logging to enable logging for additional classes, locate the `<AsyncLogger>` element that is relevant to the class in question. This class is defined in the `<AsyncLogger>` name attribute.

3. Uncomment the `<AppenderRef>` element that applies to the appender you wish to enable.

**Note:** PingAccess will rescan the logging configuration within 30 seconds and make the change active automatically.

4. Save the file.

## Write logs to other formats

You can write the audit logs to an [Oracle or SQL Server database](#).

You may also configure PingAccess to write the audit logs to a differently formatted log file that can easily be digested by [Splunk](#).

### Write logs to databases

You can enable database logging for the API, engine, and agent audit logs in `conf/log4j2.db.properties`.

### About this task

Scripts are provided in `conf/log4j/sql-scripts` to create the necessary tables. PingAccess supports logging to Oracle, SQL Server, and PostgreSQL databases.

## Steps

1. Ensure that your database driver JAR file is installed in the `PA_HOME/lib` directory. Restart PingAccess after installing the driver.
2. In `conf/log4j2.xml`, uncomment one or more of the preset appender configurations listed below:
  - **Oracle**
    - **For Administrative API audit logging:** Uncomment the `<JDBC>` element with the `name="ApiAuditLog-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Engine audit logging:** Uncomment the `<JDBC>` element with the `name="EngineAuditLog-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Agent audit logging:** Uncomment the `<JDBC>` element with the `name="AgentAuditLog-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
  - **SQL Server**
    - **For Administrative API audit logging:** Uncomment the `<JDBC>` element with the `name="ApiAuditLog-SQLServer-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Engine audit logging:** Uncomment the `<JDBC>` element with the `name="EngineAuditLog-SQLServer-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Agent audit logging:** Uncomment the `<JDBC>` element with the `name="AgentAuditLog-SQLServer-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
  - **PostgreSQL**
    - **For Administrative API audit logging:** Uncomment the `<JDBC>` element with the `name="ApiAuditLog-PostgreSQL-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Engine audit logging:** Uncomment the `<JDBC>` element with the `name="EngineAuditLog-PostgreSQL-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.
    - **For Agent audit logging:** Uncomment the `<JDBC>` element with the `name="AgentAuditLog-PostgreSQL-Database"` attribute specified, along with the following `<RollingFile>` and `<PingAccessFailover>` elements.

**Note:** The `<PingAccessFailover>` element is used to define how PingAccess logging fails over if a connection to the primary database is not accessible. Use the `retryIntervalSeconds` attribute to specify the number of seconds that must pass before retrying the primary JDBC appender.

3. In `conf/log4j2.db.properties`, replace the placeholder parameter values for each enabled appender with valid values to provide access to the database.

**Info:** You can obfuscate the password used to access the database by running either `obfuscate.sh` or `obfuscate.bat`, located in `PA_HOME/bin`. Use the database password as an argument, then copy the output into the password configuration property for the appender in `PA_HOME/conf/log4j2.db.properties`.

4. In `conf/log4j2.xml`, uncomment the `<AppenderRef>` elements in each respective `<Logger>` section as shown in the following examples:

### Oracle:

```
<!-- Audit Log Configuration-->
<Logger name="apiaudit" level="INFO" additivity="false">
  <AppenderRef ref="APIAuditLog-File"/>
  <AppenderRef ref="ApiAuditLog-Database-Failover"/>
```

```

<!--<AppenderRef ref="ApiAuditLog-SQLServer-Database-Failover"/>-->
<!--<AppenderRef ref="ApiAuditLog-PostgreSQL"/>-->
<!--<AppenderRef ref="ApiAudit2Splunk"/>-->
</Logger>
<Logger name="engineaudit" level="INFO" additivity="false">
  <AppenderRef ref="EngineAuditLog-File"/>
  <AppenderRef ref="EngineAuditLog-Database-Failover"/>
  <!--<AppenderRef ref="EngineAuditLog-SQLServer-Database-Failover"/>-->
  <!--<AppenderRef ref="EngineAuditLog-PostgreSQL"/>-->
  <!--<AppenderRef ref="EngineAudit2Splunk"/>-->
</Logger>
<Logger name="agentaudit" level="INFO" additivity="false">
  <AppenderRef ref="AgentAuditLog-File"/>
  <AppenderRef ref="AgentAuditLog-Database-Failover"/>
  <!--<AppenderRef ref="AgentAuditLog-SQLServer-Database-Failover"/>-->
  <!--<AppenderRef ref="AgentAuditLog-PostgreSQL"/>-->
  <!--<AppenderRef ref="AgentAudit2Splunk"/>-->
</Logger>

```

## SQL Server

```

<!-- Audit Log Configuration-->
<Logger name="apiaudit" level="INFO" additivity="false">
  <AppenderRef ref="APIAuditLog-File"/>
  <!--<AppenderRef ref="ApiAuditLog-Database-Failover"/>-->
  <AppenderRef ref="ApiAuditLog-SQLServer-Database-Failover"/>
  <!--<AppenderRef ref="ApiAuditLog-PostgreSQL"/>-->
  <!--<AppenderRef ref="ApiAudit2Splunk"/>-->
</Logger>
<Logger name="engineaudit" level="INFO" additivity="false">
  <AppenderRef ref="EngineAuditLog-File"/>
  <!--<AppenderRef ref="EngineAuditLog-Database-Failover"/>-->
  <AppenderRef ref="EngineAuditLog-SQLServer-Database-Failover"/>
  <!--<AppenderRef ref="EngineAuditLog-PostgreSQL"/>-->
  <!--<AppenderRef ref="EngineAudit2Splunk"/>-->
</Logger>
<Logger name="agentaudit" level="INFO" additivity="false">
  <AppenderRef ref="AgentAuditLog-File"/>
  <!--<AppenderRef ref="AgentAuditLog-Database-Failover"/>-->
  <AppenderRef ref="AgentAuditLog-SQLServer-Database-Failover"/>
  <!--<AppenderRef ref="AgentAuditLog-PostgreSQL"/>-->
  <!--<AppenderRef ref="AgentAudit2Splunk"/>-->
</Logger>

```

## PostgreSQL

```

<!-- Audit Log Configuration-->
<Logger name="apiaudit" level="INFO" additivity="false">
  <AppenderRef ref="APIAuditLog-File"/>
  <!--<AppenderRef ref="ApiAuditLog-Database-Failover"/>-->
  <!--<AppenderRef ref="ApiAuditLog-SQLServer-Database-Failover"/>-->
  <AppenderRef ref="ApiAuditLog-PostgreSQL"/>
  <!--<AppenderRef ref="ApiAudit2Splunk"/>-->
</Logger>
<Logger name="engineaudit" level="INFO" additivity="false">
  <AppenderRef ref="EngineAuditLog-File"/>
  <!--<AppenderRef ref="EngineAuditLog-Database-Failover"/>-->
  <!--<AppenderRef ref="EngineAuditLog-SQLServer-Database-Failover"/>-->
  <AppenderRef ref="EngineAuditLog-PostgreSQL"/>
  <!--<AppenderRef ref="EngineAudit2Splunk"/>-->
</Logger>
<Logger name="agentaudit" level="INFO" additivity="false">

```

```

<AppenderRef ref="AgentAuditLog-File"/>
<!--<AppenderRef ref="AgentAuditLog-Database-Failover"/>-->
<!--<AppenderRef ref="AgentAuditLog-SQLServer-Database-Failover"/>-->
<AppenderRef ref="AgentAuditLog-PostgreSQL"/>
<!--<AppenderRef ref="AgentAudit2Splunk"/>-->
</Logger>

```

5. Create the database tables. Scripts to create database tables are located in `conf/log4j/sql-scripts`.

**Note:** The scripts are written to handle the default list of elements for the relevant database log appender. Any changes to the list require corresponding changes to the SQL table creation script, or to the table itself if it already exists. For more information on working with these scripts, see Oracle, PostgreSQL, or MS SQL Server documentation.

**Important:** For PostgreSQL database scripts, use of the default **public** schema is not recommended. To run the scripts against a different schema, choose one of the following options:

- Prepend the schema before the table name. For example, `api_audit_log` would become `my_schema.api_audit_log`
- Run the script via **psql** and specify an options parameter to define the schema. For example:

```

psql postgresql://<user>@<db_hostname>:5432/<db_name>?options=--
search_path=<schema> -f api-audit-log-postgresql.sql

```

### Write audit logs for Splunk

You can configure PingAccess to write audit logs to a format for Splunk.

#### About this task

Splunk is enterprise software that allows for monitoring, reporting, and analyzing consolidated log files. Splunk captures and indexes real-time data into a single searchable repository from which reports, graphs, and other data visualization can be generated.

#### Steps

1. In `conf/log4j2.xml`, uncomment the `<RollingFile>` and `<AppenderRef>` elements for the Splunk appenders you wish to enable:

```

<!--
<RollingFile name="ApiAudit2Splunk"
    fileName="${sys:pa.home}/log/pingaccess_api_audit_splunk.log"
    filePattern="${sys:pa.home}/log/pingaccess_api_audit_splunk.
%d{yyyy-MM-dd}.log"
    ignoreExceptions="false">
    <PatternLayout>
        <pattern>%d{ISO8601} exchangeId="%X{exchangeId}"
trackingId="%X{AUDIT.trackingId}" subject="%X{AUDIT.subject}"
authMech="%X{AUDIT.auth
Mech}" client="%X{AUDIT.client}" method="%X{AUDIT.method}"
requestUri="%X{AUDIT.requestUri}" responseCode="%X{AUDIT.responseCode}"
%n</pattern>
    </PatternLayout>
    <Policies>
        <TimeBasedTriggeringPolicy />
    </Policies>
</RollingFile>
-->

```

**Note:** `<RollingFile>` elements are also present for `EngineAudit2Splunk` and `AgentAudit2Splunk`. They are structured similarly to the `ApiAudit2Splunk` example shown above.

```
<Logger name="apiaudit" level="INFO" additivity="false">
  <AppenderRef ref="APIAuditLog-File"/>
  <!--<AppenderRef ref="ApiAuditLog-Database-Failover"/>-->
  <!--<AppenderRef ref="ApiAudit2Splunk"/>-->
</Logger>
<Logger name="engineaudit" level="INFO" additivity="false">
  <AppenderRef ref="EngineAuditLog-File"/>
  <!--<AppenderRef ref="EngineAuditLog-Database-Failover"/>-->
  <!--<AppenderRef ref="EngineAudit2Splunk"/>-->
</Logger>
<Logger name="agentaudit" level="INFO" additivity="false">
  <AppenderRef ref="AgentAuditLog-File"/>
  <!--<AppenderRef ref="AgentAuditLog-Database-Failover"/>-->
  <!--<AppenderRef ref="AgentAudit2Splunk"/>-->
</Logger>
```

2. Save the file.

**Note:** PingAccess automatically updates its configuration within 30 seconds; a restart is not required for this change to be effective.

3. Download and install the Splunk Universal Forwarder on the machine running PingAccess.

4. Configure the Universal Forwarder to monitor `logs/pingaccess_api_audit_splunk.log`, `logs/pingaccess_agent_audit_splunk.log`, or `logs/pingaccess_engine_audit_splunk.log`.

**Info:** For detailed installation and configuration instructions, consult the Splunk documentation accompanying the Universal Forwarder.

## Customize and localize PingAccess

---

### Customization of user-facing pages

PingAccess supplies templates to provide information to the end user. These template pages use the Velocity template engine, an open-source Apache project, and are located in the `PA_HOME/conf/template` directory.

You can modify most of these pages in a text editor to suit the particular branding and informational needs of your PingAccess installation. (Cascading style sheets and images for these pages are included in the `PA_HOME/conf/static/pa/assets` subdirectory.) Each page contains both Velocity constructs and standard HTML. The Velocity engine interprets the commands embedded in the template page before the HTML is rendered in the user's browser. At runtime, the PingAccess server supplies values for the Velocity variables used in the template.

**Important:** If you have modified the reserved application context root using the PingAccess Admin API, file system requests to the configured reserved application context root will be translated to `/pa`. This allows the file system behavior for PingAccess resources to remain unchanged. Thus, if the reserved context root is set to `/ping`, templates and other resources would still be stored on the file system in the `pa` directory, as indicated by this document.

For information about Velocity, refer to the [Velocity project documentation](#) on the Apache Web site. Changing Velocity or JavaScript code is not recommended. The following variables are the only variables that can be used for rendering the associated Web-browser page.

Variable	Description
<code>title</code>	The browser tab title for the message. For example, Not Found.

Variable	Description
header	The header for the message. For example, Not Found.
info	The information for the message. For example, No Resource configured for request.
exchangeId	A value that identifies the request/response pair. This can be used to locate messages in the PingAccess logs.
trackingId	A value that identifies either the tracking ID (identified with a <code>tid:</code> prefix) or an Access Token ID (identified with a <code>atid:</code> prefix). This can be used to identify the session in the PingAccess and PingFederate logs.

At runtime, the user's browser is directed to the appropriate page, depending on the operation being performed and where the related condition occurs (see the table below). For example, if Rule evaluation fails, the user's browser is directed to the Policy error-handling page. The following table describes each template.

Template File Name	Purpose	Type	Action
<code>admin.error.page.template</code>	Indicates that an error occurred while the admin console was processing a request	Error	Consult <code>PA_HOME/log/pingaccess.log</code> to determine the underlying cause of the issue.
<code>general.error.page.template</code>	Indicates that an unknown error has occurred and provides an error message.	Error	Consult <code>PA_HOME/log/pingaccess.log</code> to determine the underlying cause of the issue.
<code>general.loggedout.page</code>	Displayed when a user logs out of PingAccess.	Normal	User should close the browser.
<code>oauth.error.json</code>	Indicates that Rule evaluation has failed and provides an optional error message. To customize this information, see Error-Handling Fields for OAuth Rules documentation.	Normal	If necessary, consult the audit logs in <code>PA_HOME/log</code> for details about why the policy denied the request.
<code>policy.error.page.template</code>	Indicates that Rule evaluation has failed and provides an optional error message. To customize this information, see Error-Handling Fields for Rules documentation.	Normal	If necessary, consult the audit logs in <code>PA_HOME/log</code> for details about why the policy denied the request.

**Note:** The templates stored in `PA_HOME/conf/template/system` are system templates, and should not be modified.

## Localization of user-facing pages

In addition to the use of Velocity templates to change the look and feel of user-facing pages, administrators can provide localized versions of user-facing status messages generated by PingAccess.

In `PA_HOME/conf/localization/`, properties files contain the messages to be returned to the client in various languages; by default, only English language messages are provided, using the default `pa-messages.properties` file. This file serves as a fallback for any message not found in other files in the directory.

The selection of a messages file is determined based on several different factors:

- The browser's `Accept-Language` header, based on a best-match first check against the `pa-messages` files
- The value of a cookie named `ping-accept-language`, which can be defined by the protected application
- A custom-developed PingAccess add-on that can customize the order of localization resolution

The default behavior allows the `ping-accept-language` cookie to override the browser preferences, and if that cookie is not set, then to use the `Accept-Language` header preference order, starting with the highest priority preference and trying to match the locale exactly. If none of the specified locales cannot be matched exactly, a more generic locale will be used, starting with the highest priority value.

If no matches are found, then the value in the `pa-messages.properties` file is used.

For example, suppose your browser had the following `Accept-Language` header:

```
Accept-Language: fr-CA;q=0.9, en-US;q=0.8
```

and PingAccess attempted to display a localized version of the message for:

```
pa.response.status.service.unavailable
```

The order in which PingAccess searches for the string to display is:

1. `pa-messages_fr_CA.properties`
2. `pa-messages_en_US.properties`
3. `pa-messages_fr.properties`
4. `pa-messages_en.properties`
5. `pa-messages.properties`

If the `ping-accept-language` cookie is set by the protected application to the value `en-US`, then the above list would be ignored, and PingAccess would search for the string in:

1. `pa-messages_en_US.properties`
2. `pa-messages_en.properties`
3. `pa-messages.properties`

**Important:** Most browsers support the use of an ordered list of languages, however, Safari is an exception to this. Even though the system supports an ordered list of languages, only the preferred language is sent with its requests.

# Upgrading PingAccess

---

## Upgrade PingAccess

---

### Upgrading your environment

You can upgrade your PingAccess deployment. The procedure varies depending on your environment.

- If you have a standalone PingAccess deployment not installed using the RHEL or Windows installer, use the [Upgrade a PingAccess standalone version](#) on page 91 procedure.
- If you have a PingAccess cluster, use the [Upgrade a PingAccess cluster](#) on page 92 procedure.
- If you installed PingAccess on RHEL using the installer, use the [Upgrade RHEL using the installer](#) on page 94 procedure.
- If you installed PingAccess on Windows using the installer, use the [Upgrade Windows using the installer](#) on page 93 procedure.

### Upgrade a PingAccess standalone version

You can upgrade a standalone PingAccess deployment to a newer version.

#### Before you begin

- Create a backup of your existing PingAccess configuration. If the upgrade fails, you can restore your environment from this backup.
- Review the release notes for every version between your current version and the target version.

**Important:** In release 5.0, there are potentially breaking changes to the SDK for Java, Groovy scripts, and the Administrative API. For information on these changes and the actions administrators may need to take, review the [PingAccess Release Notes for release 5.0](#).

- Verify that you have the following:
  - The PingAccess Upgrade Utility archive
  - The PingAccess distribution .zip file
  - Your PingAccess license file
  - Login access to the PingAccess host, as the utility is run on the host
  - Administrator credentials for the running PingAccess instance
- Verify that Basic Authentication is configured and enabled for the running PingAccess instance.
- Verify that the PingAccess host is running.

**Important:** If you have set `security.overridePropertiesFile=false` in `$JAVA_HOME/jre/lib/java.security`, the upgrade utility might fail, as the PingAccess Upgrade Utility uses an override to enable deprecated ciphers and protocols during the upgrade process.

#### About this task

Use the PingAccess Upgrade Utility to upgrade from PingAccess 2.1 or later (the source version) to the most recent version (the target version).

The upgrade utility starts an instance of PingAccess with an administrative listener on port 9001. This port number can be changed using the `run.bat` or `run.sh -p` parameter. This port configuration is only used for the upgrade. The default port is used by the upgraded server when the upgrade is complete.

Any warnings or errors encountered are recorded in `log/upgrade.log`, as well as on the screen while the utility is being run.

**Important:**

If your installation uses custom plugins, they will need to be rebuilt against the new (5.0) SDK. You will then run the upgrade utility manually with the new `-i` command-line option to include their plugin directory. To migrate your custom plugins, see the [PingAccess Addon SDK for Java Migration Guide](#).

**Info:** During the upgrade, it is important to not make any changes to the running PingAccess environment.

**Steps**

1. Copy the upgrade utility `.zip` file to the PingAccess host and extract it.
2. Change to the upgrade utility's `bin` directory.
3. Run the PingAccess Upgrade Utility:

- On Windows: `run.bat [-p <admin_port>] [-i <directory>] <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`
- On Linux: `./run.sh [-p <admin_port>] [-i <directory>] <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`

For example: `./run.sh -p 9002 -i MyJARDir pingaccess-4.3 pingaccess-5.0 pingaccess-5.0.zip pingaccess50.lic`

**Parameter definitions**

The command-line parameters are the same regardless of the platform, and are defined as follows:

Parameter	Value description
<code>&lt;admin_port&gt;</code>	Optional port to be used by the temporary PingAccess instance run during the upgrade. The default is 9001.
<code>&lt;directory&gt;</code>	A directory containing additional library JAR files (e.g. plugins, JDBC drivers) to be copied into the target installation
<code>&lt;sourcePingAccessRootDir&gt;</code>	The PA_HOME for the source PingAccess version
<code>&lt;outputDir&gt;</code>	The target directory which will contain the unpacked PingAccess distribution
<code>&lt;pingaccessZip&gt;</code>	The PingAccess distribution for the target version
<code>&lt;newPingAccessLicense&gt;</code>	The path to the PingAccess license file to use for the target version

**Next steps**

After you have completed the upgrade, [Perform post-upgrade tasks](#) on page 95.

**Upgrade a PingAccess cluster**

You can upgrade a PingAccess cluster to a newer version.

**Before you begin**

- Create a backup of your existing PingAccess configuration. If the upgrade fails, you can restore your environment from this backup.
- Review the release notes for every version between your current version and the target version.

**Important:** In release 5.0, there are potentially breaking changes to the SDK for Java, Groovy scripts, and the Administrative API. For information on these changes and the actions administrators may need to take, review the [PingAccess Release Notes for release 5.0](#).

- Verify that each node is using the same PingAccess version. You can check the version by viewing the `<PA_HOME>/pingaccess-admin-ui-<version number>.jar` file.
- Verify that the PingAccess administrative node is running.
- Verify that basic authentication is configured and enabled for the running PingAccess administrative node.

### About this task

To upgrade a cluster, perform the following steps:

### Steps

1. On the administrative node, extract the upgrade utility .zip file.
2. Change to the upgrade utility's bin directory.
3. Run the PingAccess upgrade utility:
  - On Windows: `run.bat [-p <admin_port>] [-i <directory>] <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`
  - On Linux: `./run.sh [-p <admin_port>] [-i <directory>] <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`
4. Review the upgrade log. If it records any manual post-upgrade tasks, perform these steps:
  - a) Open the `run.properties` file and change the upgraded administrative console's `admin.port` and `clusterconfig.port` values to a temporary value. This file is in the `<PA_HOME>/conf/` directory on Linux systems and the `<PA_HOME>\conf\` directory on Windows systems.
  - b) Start the upgraded administrative console using the `<PA_HOME>/bin/run.sh` command on Linux systems or the `<PA_HOME>\bin\run.bat` command on Windows systems.
  - c) Perform any manual post-upgrade tasks recorded in the upgrade log.
  - d) Shut down the upgraded administrative console.
  - e) Change the upgraded administrative console's `admin.port` and `clusterconfig.port` values back to the original values.
5. Run the upgrade utility on each engine node.
6. Shut down the entire cluster.
7. Start the upgraded administrative node.
8. Start each upgraded engine node.

### Next steps

After you have completed the upgrade, [Perform post-upgrade tasks](#) on page 95.

## Upgrade Windows using the installer

If you installed PingAccess using the Windows installer, use this procedure to upgrade using the installer.

### About this task

**Important:** If additional JAR files (such as custom plugins and JDBC drivers) have been added to the existing PingAccess `/lib` directory, the 5.0-Beta installer cannot be used to perform the upgrade. Instead, run the upgrade utility manually, using the `-i` command-line option to specify the JAR files to be included.

## Steps

1. Download the installer.
2. Start the installer. The existing installation is detected.
3. Choose **Yes** to upgrade the installation.
4. Choose a license file and specify a temporary admin port. Click **Next**.

**Note:** The temporary admin port is not required when upgrading a cluster node.

5. Specify the administrator credentials. Click **Next**.

**Note:** Administrator credentials are not required when upgrading a cluster node.

6. Click **Finish**.

## Next steps

After you have completed the upgrade, [Perform post-upgrade tasks](#) on page 95.

## Upgrade RHEL using the installer

If you installed PingAccess using the RHEL installer, use this procedure to upgrade using the installer.

### About this task

**Note:** On supported systems, you are given the option to upgrade your existing `systemv` scripting service to the newer `systemd` service. Upgrading the service will replace the existing service.

**Important:** If additional JAR files (such as custom plugins and JDBC drivers) have been added to the existing `PingAccess/lib` directory, the 5.0-Beta installer cannot be used to perform the upgrade. Instead, the Upgrade Utility should be run manually, using the `-i` command-line option to specify the JAR files to be included.

## Steps

1. Download the installer script.
2. Launch the script using the command `sudo -E ./pa-install-<version>.sh -u`.
3. Specify the instance you want to upgrade.

**Important:** If you are upgrading a PingAccess cluster, always upgrade the console first.

4. Confirm the selection.
5. Specify a license file.
6. Specify the temporary admin port.

**Note:** The temporary admin port is not required when upgrading a cluster node.

7. Specify whether you have additional plugin or JDBC driver JAR files to include during upgrade.

**Note:** This step is required when plugin JARs are present and you are upgrading to a version that is not SDK backward-compatible. For more information, see [Upgrade a PingAccess standalone version](#) on page 91 and the [PingAccess Addon SDK for Java Migration Guide](#).

8. If you selected `yes` to include additional JAR files, enter the path to the `include` directory. The JAR files in this directory will be copied into the new PingAccess installation instead of migrating additional library JARs from the existing installation.
9. Provide the administrator credentials.

**Note:** Administrator credentials are not required when upgrading a cluster node.

10. Allow the upgrade to complete.

## Next steps

After you have completed the upgrade, [Perform post-upgrade tasks](#) on page 95.

## Perform post-upgrade tasks

After you have upgraded your PingAccess deployment using the upgrade utility or the installer, you must perform several post-upgrade tasks to ensure that the target version works correctly.

### About this task

To see details about the upgrade, examine `log/upgrade.log`. To see details about the migrated configuration data, examine `log/audit.log`.

After the upgrade utility or installer has completed, perform the following steps:

### Steps

1. Review any warnings returned by the upgrade utility and take the actions indicated in the table below.

At the end of an upgrade, the PingAccess Upgrade Utility or installer records any manual steps that require user intervention both in the command-line output and in `log/upgrade.log` at the WARN level. Information that does not require user intervention is added to the `log/upgrade.log` at the INFO level.

2. Generate new obfuscated passwords for the `pa.jdbc.password`, `pa.jdbc.filepassword`, and `pa.keystore.pw` parameters in `conf/run.properties`:

- If you are on a Linux host, run this command:

```
obfuscafe.sh password
```

- If you are on a Windows host, run this command:

```
obfuscate.bat password
```

3. Copy the obfuscated password and paste it into the parameter in `run.properties` that corresponds to the password being re-obfuscated.
4. Review the HTTP requests configuration to ensure the use of the IP source settings is appropriate for the environment. During the upgrade process, the *List Value Location* setting is changed from the default of Last to First to match the behavior from earlier releases.
5. Stop the source version of PingAccess.
6. Start the target version of PingAccess.

Warning text	Steps to take
Resource ' <i>ResourceName</i> ' contains an invalid path prefix and cannot be migrated to the target version. Manual intervention is required.	This occurs when the 2.1 path prefix contains functionality supported via a Java regex, but not by the wild card support in 3.1. The user must manually migrate the regex to 1 or more path prefixes in 3.1. For example, consider the 2.1 prefix, <code>/(app1 app2)</code> . This can be translated to a single resource in 3.1.1 with path prefixes of <code>/app1</code> and <code>/app2</code> .

Warning text	Steps to take
<p>Resource '<i>ResourceName</i>' requires a case-sensitive path. This conflicts with its containing Application, which requires a case-insensitive path. Manual intervention may be required.</p>	<p>The upgrade utility identifies path prefixes in 2.1 that start with <code>/(?i)</code> as path prefixes that are case-insensitive, and sets the case-sensitivity flag on the application appropriately. However, if multiple resources in a new application use inconsistent case sensitivity settings, the utility cannot determine what the case sensitivity should be. 2.1 resources are case-sensitive by default.</p>
<p>Resource '<i>ResourceName</i>' requires a case-insensitive path. This conflicts with its containing Application, which requires a case-sensitive path. Manual intervention may be required.</p>	<p>This is the same as the previous setting, but with the requirement being for a case-insensitive path rather than a case-sensitive one.</p>
<p>Resource '<i>ResourceName</i>' is disabled in the source version. Resources can no longer be individually disabled. Application '<i>ApplicationName</i>' has been disabled due to this constraint.</p>	<p>In 2.1, individual resources can be disabled. In 3.1, only applications can be enabled or disabled. The upgrade utility takes the approach of disabling the application if any related resources are disabled. Check the final configuration and make sure this is the desired outcome. If it is not, the disabled resources need to be deleted, and the application needs to be enabled.</p>
<p>Path prefix for Resource '<i>ResourceName</i>' contains a '.' character. This will be treated as a literal '.' in the target version.</p>	<p>In a 2.1 setup, there might be resource names that accidentally contain a '.', assuming it is a literal '.' rather than part of a regex. For example, any file extension type resources will probably not be escaping the '.'. This message is intended to bring this change in semantics to the user's attention. This action item will not show up if the user has correctly escaped the '.' character with the '\.' sequence.</p>

Warning text	Steps to take
<p>Resource '<i>ResourceName</i>' could not be migrated to the target version due to Application context root conflicts. Manual intervention is required.</p>	<p>This message indicates that multiple resources that use the same virtual host, but a different web session or site must be mapped under the same context root in the same application to preserve semantics. For example, consider the following configuration:</p> <ul style="list-style-type: none"> <li>• Resource A: <ul style="list-style-type: none"> <li>• Path Prefix: /hr</li> <li>• Virtual Host: internal.example.com</li> <li>• Web Session: W</li> <li>• Site: Z</li> </ul> </li> <li>• Resource B: <ul style="list-style-type: none"> <li>• Path Prefix: /sales</li> <li>• Virtual host: internal.example.com</li> <li>• Web Session: W</li> <li>• Site: Z</li> </ul> </li> <li>• Resource C: <ul style="list-style-type: none"> <li>• Path Prefix: /payroll</li> <li>• Virtual Host: internal.example.com</li> <li>• Web Session: V</li> <li>• Site: Z</li> </ul> </li> </ul> <p>This configuration triggers this error because these resources cannot be grouped in the same application, but they would need to be in order to preserve the semantics in the internal.example.com address space. This issue could be fixed by using rewrite rules to place Resource C or Resources A and B under a different namespace. For example, use /intranet/sales and /intranet/hr on the front-end and rewrite out the /intranet on the backend.</p>
<p>Application '<i>ApplicationName</i>' contains OAuth rules, but authenticates users with a web session. Unexpected results may occur.</p>	<p>2.1 allows OAuth rules to be attached resources that use a web session. While this configuration is likely invalid in the first place, it would be possible to include both a PA cookie and OAuth token in requests and PA would apply policy to the requests as configured. In 3.1, however, an API application and web application are mutually exclusive so the semantics of this particular configuration cannot be preserved.</p>

Warning text	Steps to take
<p>The resource order for Virtual Host '<i>VirtualHostName</i>' has changed in the target version.</p>	<p>The upgrade utility checks that the resource order is consistent before and after the upgrade. This message indicates that the resource order from 2.1 does not match 3.1. This is likely due to how context roots in applications are ordered in 3.1. For 3.1, applications are ordered based on their context root, where the longest context root is checked first during resource matching.</p> <p>One way to address this is to review and potentially change the application context root values associated with the virtual host to avoid URL overlaps between applications.</p>
<p>Application '<i>ApplicationName</i>' is no longer associated with an Identity Mapping. A Web Session or an Authorization Server is required to use Identity Mappings.</p>	<p>Indicates a misconfiguration in the source version. Check whether you intended to use an Identity Mapping for the application and associate an appropriate Web Session or Authorization Server if necessary.</p>
<p>OAuth Rule with id '<i>RuleId</i>' is no longer associated with Application '<i>ApplicationName</i>' because Application '<i>ApplicationName</i>' is not an OAuth Application. Manual intervention may be required.</p>	<p>Indicates a misconfiguration in the source version. Check whether the OAuth Rule is necessary to implement the desired Access Control policy.</p>
<p>OAuth RuleSet with id '<i>RuleSetId</i>' is no longer associated with Application '<i>ApplicationName</i>' because Application '<i>ApplicationName</i>' is not an OAuth Application. Manual intervention may be required.</p>	<p>Indicates a misconfiguration in the source version. Check whether the OAuth RuleSet is necessary to implement the desired Access Control policy.</p>
<p>Resource '<i>ResourceName</i>' from Application with id '<i>ApplicationId</i>' was not migrated because the Application is a Web Application while the Resource has OAuth Rules. Manual intervention may be required.</p>	<p>Indicates a Resource associated with the Application is associated with OAuth Rules. This is likely a misconfiguration, and it is necessary to evaluate whether this was intended or not.</p>
<p>Upgrade created 'Availability Profile for Site '<i>SiteName</i>'. A more descriptive name may be required.</p>	<p>Indicates that an Availability Profile was created for the Site during the upgrade. You may want to give the Availability Profile a more descriptive name.</p>
<p>Application '<i>ApplicationName</i>' and associated Resources were not migrated. The context root of <i>/pa</i> is reserved. Manual intervention may be required.</p>	<p>The <i>/pa</i> context root was allowed as a valid context root in PingAccess 3.0 and is no longer allowed.</p>
<p>Resource '<i>ResourceName</i>' from Application with id '<i>ApplicationId</i>' was not migrated because the <i>/pa</i> prefix is reserved when the Application context root is <i>/</i>. Manual intervention may be required.</p>	<p>The <i>/pa</i> path prefix was allowed as a valid path prefix in PingAccess 3.0 and is no longer allowed.</p>

Warning text	Steps to take
<p>The OAuth Groovy Script Rule no longer controls the realm in the response sent for an unauthorized OAuth request.</p>	<p>With PingAccess 3.2, Realms have been moved to the Application. The <i>Realm</i> can still be set using the PingAccess Admin API interface. With the change in context for how realms are applied, it is necessary to check existing OAuth Groovy Rules to ensure that they behave as expected. This message is shown if any OAuth Groovy Rules exist in the migrated configuration.</p>
<p>The property '<i>PropertyName</i>' was set to a blank value to maintain compatibility. However, it is recommended that this be set to '<i>PropertyName=PropertyValue</i>'</p>	<p>New Security Headers properties values are not set during an upgrade in order to preserve the behavior from the source release in the upgrade. If there is no reason not to in your environment, update <code>run.properties</code> with the recommended setting.</p>
<p>As a security enhancement, the default value of '<i>CipherList</i>' has changed with this version of PingAccess. Your existing ciphers remain unchanged. However, it is recommended to use the default value: '<i>PropertyName=CipherList</i>'.</p>	<p>This message applies to the <code>admin.ssl.ciphers</code>, <code>engine.ssl.ciphers</code>, and <code>agent.ssl.ciphers</code> lists. This message is displayed if the upgrade source version cipher lists are changed from the defaults. We recommend updating the configuration with the new default value if possible.</p>
<p>The property '<i>PropertyName</i>' was set to a blank value to maintain compatibility. However, it is recommended that this be set to '<i>PropertyName=CipherList</i>'</p>	<p>This message applies to the <code>site.ssl.protocols</code>, <code>site.ssl.ciphers</code>, <code>pf.ssl.protocols</code>, and <code>pf.ssl.ciphers</code> settings. The upgrade utility sets these values as empty values in order to maintain backwards compatibility, but the recommended value should be used if possible.</p>
<p>The host for VirtualHost <code>VirtualHost:Port</code> already has a KeyPair associated with it. The KeyPair previously associated with this VirtualHost was removed. Only one KeyPair can be associated with a given host.</p>	<p>If a Virtual Host has more than one key pair associated with it, only one key pair will be associated with it after the upgrade completes. This message is displayed to indicate which key pair was used.</p>
<p>Application with name '<i>ApplicationName</i>' not migrated as the context root '<i>Path</i>' was a reserved path.</p>	<p>If an application's context root is a reserved PingAccess path, the application will not be migrated. The indicated application will need to be created with a context root that does not conflict with the reserved path.</p>
<p>Resource with name '<i>ResourceName</i>' not migrated as the path '<i>Path</i>' was a reserved path.</p>	<p>If a Resource path is a reserved PingAccess path, the application will not be migrated. The indicated application will need to be created with a context root that does not conflict with the reserved path.</p>
<p>The CIDR Rule with name '<i>RuleName</i>' is associated with an Agent Application named '<i>ApplicationName</i>' and overrides the IP source configuration. A new Agent rule should be created that does not override the IP source.</p>	<p>With changes in IP source header handling, additional options are available to override the headers used to identify the source address. When an agent is involved, the changes in IP source handling may cause the specified rule to not behave as expected.</p>

Warning text	Steps to take
<p>Require HTTPS option on Application '<i>ApplicationName</i>' was set to <i>Setting</i> as Virtual Host had port <i>Port</i>. Please verify this setting is correct.</p>	<p>The upgrade utility attempts to set the Require HTTPS option based on the virtual host associated with an application during an upgrade. This message is an advisory to just verify that the setting was properly detected.</p>
<p>VirtualHost '<i>VirtualHost</i>' was not migrated. An existing VirtualHost existed with the same logical name '<i>VirtualHost</i>'.</p>	<p>Virtual host names are now case-insensitive. During the upgrade, after making the names case-insensitive, a duplicate virtual host was identified. It will be necessary to either recreate the virtual host with a new name, or to modify the configuration so the proper virtual host is migrated to the upgraded system.</p>
<p>Renamed Virtual Host's Hostname from '<i>VirtualHost</i>' to '<i>NewVirtualHost</i>' due to virtual host spec compliance issue</p>	<p>If a Virtual Host name contains an underscore (<code>_</code>) character, that does not conform to host naming requirements. In this instance, the underscore will be renamed to the string <i>a-z</i>. For example, if a Virtual Host named <i>my_virtual_host</i> is migrated, the new name will be <i>mya-zvirtuala-zhost</i>.</p>
<p>Removed Http Request Rule with name '<i>RuleName</i>', this Rule must be converted to a groovy script rule. Manual intervention may be required.</p>	<p>When an HTTP request rule is migrated from an earlier release of PingAccess, rules that specify a source of <i>Body</i> are not migrated. A Groovy script rule can be used to perform a similar match, but the details of such a Groovy script require administrator intervention.</p> <p>A simple Groovy script rule that would perform a similar function might be:</p>
	<pre>requestBodyContains('value')</pre>
	<p>We advise, however, that a script be constructed that performs additional validation in order to ensure the rule passes only when desired; a generic match like this could lead to unexpected results depending on what content might be in the request body.</p>

Warning text	Steps to take
<p>The property '<i>PropertyName</i>' uses a customized value. "Your original value has not been modified. You may encounter startup or connection problems if this value is not supported by the JVM.</p>	<p>When migrating SSL settings between versions of PingAccess that use different JVM or JDK versions, custom settings might not be compatible. If the protocols or ciphers used are not compatible with the target JVM or JDK, this message indicates which settings need to be manually updated.</p> <p>The <i>PropertyName</i> value can be any of the following values:</p> <ul style="list-style-type: none"> <li>• site.ssl.protocols</li> <li>• site.ssl.ciphers</li> <li>• pf.ssl.protocols</li> <li>• pf.ssl.ciphers</li> <li>• admin.ssl.protocols</li> <li>• admin.ssl.ciphers</li> <li>• engine.ssl.protocols</li> <li>• engine.ssl.ciphers</li> <li>• agent.ssl.protocols</li> <li>• agent.ssl.ciphers</li> </ul>
<p>Rule with ID <i>RuleId</i> and name '<i>RuleName</i>' was not migrated as matcher was invalid for the Groovy rule type.</p> <p>Invalid rules were removed from RuleSet '<i>RuleSetName</i>' which resulted in an empty set.</p> <p><i>The RuleSet was removed. Please check your policy configuration.</i></p> <p>Invalid rules were removed from RuleSet '<i>RuleSetName</i>'. Please check your policy configuration.</p> <p>Invalid Rules were removed from Application '<i>ApplicationName</i>'. Please check your policy configuration.</p> <p>Invalid RuleSets were removed from Application '<i>ApplicationName</i>'. Please check your policy configuration.</p> <p>Invalid Rules were removed from Resource '<i>resource name</i>' on Application '<i>ApplicationName</i>'. Please check your policy configuration.</p> <p>Invalid RuleSets were removed from Resource '<i>resource name</i>' on Application '<i>ApplicationName</i>'. Please check your policy configuration.</p>	<p>These messages may be displayed if the source PingAccess installation has misconfigured Groovy Rules.</p> <p>This indicates that you are not permitted to add an OAuth rule to an Application of type Web, by editing an existing Rule Set.</p> <p>Groovy or OAuth Groovy rules will not be migrated for the following reasons:</p> <ul style="list-style-type: none"> <li>• The OAuth Groovy rule was applied to a Web application.</li> <li>• The Groovy or OAuth Groovy uses a matcher that is not appropriate for the application type.</li> </ul> <p>Check the policy configuration.</p>

Warning text	Steps to take
<p>Rule with name '<i>RuleName</i>' has been removed from RuleSet with name '<i>RuleSetName</i>'. Multiple Rate Limiting Rules with the same Policy Granularity cannot be included in a RuleSet."</p>	<p>The upgrade utility supports migrating a RuleSet containing multiple CORS or Rate Limiting rules with the same Policy Granularity. The upgrade utility will generate new action items, indicating that rules were removed from a RuleSet.</p>
<p>Rule with name '<i>RuleName</i>' has been removed from RuleSet with name '<i>RuleSetName</i>'. Multiple Cross-Origin Request Rules cannot be included in a RuleSet."</p>	<p>These messages indicate that if both rules exist, there is a restriction to a single Rate Limiting or CORS rule. Please check to confirm that you have applied the correct rule to the policy.</p>
<p>One or more notifications were issued while migrating from version <i>SOURCE</i> to version <i>TARGET</i></p> <p>Setting clusterconfig.enabled to false</p> <p>The new configuration query port feature has been disabled for backward compatibility. Please refer to the PingAccess clustering documentation before enabling this feature.</p>	<p>The new cluster config query port is enabled by default for new PingAccess 4.0 installations when running in CLUSTERED_CONSOLE or CLUSTERED_CONSOLE_REPLICA mode.</p> <p>During the upgrade process to version 4.0, the new cluster config query port is disabled. Messages are written to <code>upgrade.log</code> and <code>audit.log</code> to indicate this cluster configuration change was made.</p> <p>Please refer to the PingAccess clustering documentation before enabling this feature.</p>
<p>One or more notifications were issued while migrating from version <i>SOURCE</i> to version <i>TARGET</i></p> <p>For backward compatibility, when connecting to a protected, TLS SNI-enabled Site, PingAccess will set the SNI <code>server_name</code> to the configured target host and not the HTTP request Host header value. Please refer to PingAccess' upgrade documentation for more information.</p>	<p>During upgrades to release 4.0 and higher, the Upgrade Utility sets the value of <code>pa.site.tls.sni.legacyMode</code> to <code>true</code> to maintain compatibility with existing configurations. This property is controlled in the <code>run.properties</code> file and is not enabled on new installs.</p>
<p>Localization property '<i>{property name}</i>' was added to <code>pa-messages.properties</code>. Any customized localization files should be updated.</p>	<p>This message will appear if new language properties are added between the source and target PA versions and you have added additional language files or modified the <code>en</code> or <code>en_US</code> files. Update any customized files as required.</p>
<p>Localization property '<i>{property name}</i>' in <code>pa-messages.properties</code> was modified. Any customized localization files should be updated.</p>	<p>This message will appear if the language properties have changed between the source and target PA versions and you have added additional language files or modified the <code>en</code> or <code>en_US</code> files. Update any customized files as required.</p>
<p>Localization property '<i>{property name}</i>' was removed from <code>pa-messages.properties</code>. This property can be removed from any customized localization files.</p>	<p>This message will appear if the language properties have been removed between the source and target PA versions and you have added additional language files or modified the <code>en</code> or <code>en_US</code> files. Update any customized files as required.</p>

Warning text	Steps to take
<p>WebSessionManagement contained an invalid cookie name. Replaced '{old cookie name}' with '{new cookie name}'. Please validate your configuration.</p>	<p>This message will appear if the WebSessionManagement has an invalid cookie name. Invalid characters are replaced with an underscore. Update any references as required.</p>
<p>Legacy authentication requirements policy evaluation has been enabled to maintain backward compatibility with earlier versions of PingAccess. To disable this setting, remove the pa.policy.eval.acr.v42 property from run.properties.</p>	<p>This message will appear on upgrade to release 4.3 or higher if you have one or more authentication requirements rules. You can make adjustments to configured rules so you can remove this property or you can maintain the property to leave existing rules unaffected.</p>
<p>Property pa.audit.log.applicationResourceIdsAsIntegers was set to true in run.properties to maintain existing behavior. In order to log the ID of Global Unprotected Resources, this property should be removed or should be set to false (default). However, a value of false (default) will result in resourceId and applicationId audit logging fields being logged as strings, not integers, which may require audit logging database schema changes if these values are currently being used.</p>	<p>This message will appear on upgrade to release 5.1 or higher to support the existing logging behavior of application resource IDs as integers. The default behavior of release 5.1 and higher is to log these IDs as strings. You can choose to log application resource IDs as strings after the upgrade by removing, or setting to false, the applicable property in run.properties. This change may require a modification to the audit logging database schema.</p>
<p>Invalid resource method 'Method' was removed from Resource 'ResourceName' on Application 'ApplicationName'.</p>	<p>This message will appear on upgrade to release 5.3 or later if the source version has an application resource that contains a method with whitespace. The resource is preserved by the upgrade, but the method is removed.</p>
<p>Invalid Resource {name} on Application {name} was removed because it did not have any valid methods.</p>	<p>This message will appear on upgrade to release 5.3 or later if all of the methods associated with a resource were removed with an Invalid resource method error. The resource is not migrated by the upgrade.</p>

## Restore a PingAccess configuration backup

If an upgrade fails, you can restore your PingAccess configuration using an automatically generated backup.

### About this task

PingAccess automatically creates a backup zip file each time an Administrative user authenticates to the administrative console. These backups are stored in `PA_HOME/data/archive`, with a maximum number of backups configurable using the `pa.backup.filesToKeep` configuration parameter in `run.properties`.

**CAUTION:** This operation will replace your current configuration settings.

## Steps

1. Stop PingAccess.
2. Unzip the backup file to `PA_HOME` .
3. Restart PingAccess.

## Results

Your PingAccess configuration will now be reverted to the state in the backup archive that was restored.

# PingAccess: Zero Downtime Upgrade

## Introduction

This document describes the steps required to perform a zero downtime upgrade of a PingAccess cluster to version 5.0 or higher. A zero downtime upgrade allows you to upgrade your environment with no impact to resource availability or existing user sessions.

Though this procedure is applicable to any PingAccess cluster upgrade to version 5.0 or higher, there are minor variations depending on your PingAccess source version. Those variations are clearly described where applicable.

Note that there are some steps, particularly those related to working with a load balancer, that are dependent on your environment. It is expected that you are familiar with the tasks required by these steps and, accordingly, this document does not attempt to offer detailed instruction on performing these tasks.

**Important:** In order to achieve a successful upgrade, perform the steps in this document in the order that they are presented. Deviation from these steps may result in a failed upgrade and/or system downtime.

To begin the upgrade process, [Disable key rolling](#) to prevent active sessions from being invalidated.

## Step 1: Disable key rolling

In this step, you will disable key rolling to prevent active sessions from being invalidated during the upgrade process. This is a temporary modification that you will address when the upgrade is complete. Note that there are different procedures at this stage depending if your source version is [PingAccess 5.0](#) or an [earlier version of PingAccess](#).

### Source version of PingAccess 5.0 and higher

If the source is PingAccess 5.0 or higher, you can disable key rolling.

1. Navigate to **Settings > Access > Identity Mappings**.
2. In the **Auth Token Management** section, deselect **Key Roll Enabled**.

3. Click **Save**.
4. Navigate to **Settings > Access > Web Sessions**.
5. In the **Web Session Management** section, deselect **Key Roll Enabled**.
6. Click **Save**.
7. Navigate to **Settings > System > Token Validation**.
8. In the **OAuth Key Management** section, deselect **Key Roll Enabled**.
9. Click **Save**.

### Source is an earlier version of PingAccess

If the source is a version of PingAccess earlier than 5.0, you can set the key rolling interval to a value that allows enough time for the upgrade to be completed successfully.

1. Navigate to **Settings > Access > Identity Mappings**.
2. In the **Auth Token Management** section, specify a **Key Roll Interval** of 240 (10 days).
3. Click **Save**.
4. Navigate to **Settings > Access > Web Sessions**.
5. In the **Web Session Management** section, specify a **Key Roll interval** of 240 (10 days).
6. Click **Save**.

Next, you will [upgrade the Admin node](#).

## Step 2: Upgrade the Admin node

In this step, you will upgrade the PingAccess administration node using the PingAccess Upgrade Utility. As part of this step, you will use the `-r` switch to disable configuration replication on the target version.

For more information on upgrading PingAccess, see [Upgrade PingAccess](#).

### Prerequisites

Prior to beginning the upgrade process, make sure you have:

- Ensured PingAccess is running
- Downloaded and unpacked the PingAccess [Upgrade Utility](#)
- Downloaded the PingAccess [distribution ZIP file](#)
- The PingAccess license
- Administrator credentials
- Basic Authentication enabled

**Warning:** Failure to enable basic authentication can result in losing access to the Administration console.

### Upgrade the PingAccess administrative node

1. To run the Upgrade Utility, use a command line to change to the Upgrade Utility's `/bin` directory. For example:

```
cd /pa-upgrade-5.0.1/bin
```

2. Run the Upgrade Utility:

- Linux: `./run.sh -r <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`

For example:

```
./run.sh -r ../pingaccess-4.3.0 ../pingaccess-5.0.1 ../pingaccess-5.0.1.zip ../pingaccess.lic
```

- Windows: `run.bat -r <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`

For example:

```
run.bat -r ../pingaccess-4.3.0 ../pingaccess-5.0.1 ../pingaccess-5.0.1.zip ../pingaccess.lic
```

**Important:** The `-r` switch will disable configuration replication on the Admin node. You will re-enable configuration replication after the Admin and all engine nodes have been upgraded.

3. Stop the existing PingAccess admin instance.
4. Start the new PingAccess admin instance.
5. Upgrade the Admin Replica node using the same steps, but omitting the `-r` switch.

**Important:** If PingAccess is running as a service:

- In Linux, update **PA\_HOME** in `/etc/systemd/system/pingaccess.service` to point to the new installation.
- In Windows, remove the existing PingAccess service (`<OLD_PA_HOME>\sbin\Windows\uninstall-service.bat`) and add the new service (`<NEW_PA_HOME>\sbin\Windows\install-service.bat`).

After you have upgraded the Admin and Replica Admin nodes, you can begin [upgrading the engines](#).

### Step 3: Upgrade engines

This phase of the zero downtime upgrade focuses on upgrading each engine in the cluster. To maintain resource availability, you perform this set of steps on **one engine at a time** until all engines are successfully upgraded.

**Important:** It is imperative that you perform these steps on one engine at a time to maintain availability. Engines are identified by the engine name. Ensure that the engine that you remove from the load balancer aligns with the engine definition you import.

This phase requires that the following steps take place for each engine in the cluster, **one at a time**:

- [Remove the engine from the load balancer](#)
- [Upgrade the engine](#)
- [Resume configuration replication](#) on page 108
- [Add the engine to the load balancer](#)

**Important:** Do not begin the upgrade of an additional engine until the active engine upgrade is completed and the engine is reporting to the PingAccess administrative node.

## Remove the engine from the load balancer configuration

This step requires you to remove the engine from the load balancer configuration. Since this step is dependent on your environment, no specific instruction will be provided. It is assumed that you are familiar with the steps required to temporarily remove the engine from your load balancer configuration.

**Important:** To maintain resource availability, you should remove only the engine you are upgrading. After the upgrade is complete, you will add the engine back to the load balancer configuration. Only after you confirm that the engine has been successfully added to the load balancer and is reporting properly to PingAccess should you begin the upgrade process on additional engines.

## Remove the engine from the load balancer configuration

1. Identify and note the engine you want to upgrade. Ensure you have the engine definition for this engine available.
2. Locate the entry for this engine in your load balancer configuration.
3. Depending on your environment, you may be removing this entry or you may be commenting the entry to remove it. Ensure that you make note of any entries you remove or modify so that you can reverse this operation later in [Add the engine to the load balancer configuration](#) on page 109.
4. Remove the engine entry from the load balancer.
5. Restart the load balancer.

## Upgrade the engine

In this step, you will use the PingAccess Upgrade Utility to upgrade the engine.

For more information on upgrading PingAccess, see [Upgrade PingAccess](#).

## Prerequisites

Prior to beginning the upgrade process, make sure you have:

- Ensured the PingAccess engine is running
- Downloaded and unpacked the PingAccess [Upgrade Utility](#)

- Downloaded the PingAccess [distribution ZIP file](#)
- The PingAccess license

### Upgrade the PingAccess engine

1. To run the Upgrade Utility, use a command line to change to the Upgrade Utility's `/bin` directory. For example:

```
cd /pa-upgrade-5.0.1/bin
```

2. Run the Upgrade Utility:

- Linux: `./run.sh <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`

For example:

```
/run.sh ../pingaccess-4.3.0 ../pingaccess-5.0.1 ../pingaccess-5.0.1.zip ../pingaccess.lic
```

- Windows: `run.bat <sourcePingAccessRootDir> <outputDir> <pingaccessZip> <newPingAccessLicense>`

For example:

```
run.bat ../pingaccess-4.3.0 ../pingaccess-5.0.1 ../pingaccess-5.0.1.zip ../pingaccess.lic
```

3. Stop the existing PingAccess instance. Do not start the new instance.

**Important:** If PingAccess is running as a service:

- In Linux, update **PA\_HOME** in `/etc/systemd/system/pingaccess.service` to point to the new installation.
- In Windows, remove the existing PingAccess service (`<OLD_PA_HOME>\sbin\Windows\uninstall-service.bat`) and add the new service (`<NEW_PA_HOME>\sbin\Windows\install-service.bat`).

### Resume configuration replication

In this step, you will resume configuration replication that was disabled by the Upgrade Utility. You will perform this step for the Admin replica and all engines in the cluster. You will use the PingAccess Admin API to GET and PUT the relevant configuration data for each of these items.

### To resume configuration replication:

**Note:** Perform the following steps for the Replica Admin node and for each engine in the cluster.

1. In a browser, navigate to `https://<PingAccessHost>:9000/pa-admin-api/v3/api-docs/`.
2. For engines, expand the `/engines` endpoint.

3. Click the **GET /engines** operation.
4. Click **Try it out!** and note the engine `id` for each engine.
5. Click the **GET /engines/{id}** operation.
6. Enter the `id` of the engine you want to update and click **Try it out!**
7. Copy the **Response Body**.
8. Click the **PUT /engines/{id}** operation and enter the `id` of the engine you want to update.
9. Paste the **Response Body** you copied and change `"configReplicationEnabled"` to `true`.
10. Click **Try it out!**

If the operation is successful, you will receive a **Response Code** of **200**.

11. Repeat the previous steps for each engine.
12. In the PingAccess administration console, navigate to **Settings > System > Clustering**.
13. Ensure the engines are displayed and reporting. A healthy engine shows a green status indicator.

**Note:** There may be a delay in bringing the engine to a running status. If the engine does not immediately show as reporting, refresh the page until the engine status indicator is green (running).

14. Expand the `/adminConfig/replicaAdmins` endpoint.
15. Click the **GET /adminConfig/replicaAdmins** operation.
16. Click **Try it out!** and note the `id` for the replica admin.
17. Click the **GET /adminConfig/replicaAdmins/{id}** operation.
18. Enter the `id` of the replica admin you want to update and click **Try it out!**
19. Copy the **Response Body**.
20. Click the **PUT /adminConfig/replicaAdmins/{id}** operation and enter the `id` of the replica admin you want to update.
21. Paste the **Response Body** you copied and change `"configReplicationEnabled"` to `true`.
22. Click **Try it out!**

If the operation is successful, you will receive a **Response Code** of **200**.

23. In the PingAccess administration console, navigate to **Settings > System > Clustering**.
24. Ensure the **Replica Administrative Node** displayed and reporting on the **Administrative Nodes** screen. A healthy node shows a green status indicator.

### Add the engine to the load balancer configuration

This step requires you to add the engine back to the load balancer configuration. Since this step is dependent on your environment, no specific instruction will be provided. It is assumed that you are familiar with the steps required to add the engine back to the load balancer configuration.

After you confirm that the engine has been successfully added to the load balancer and is reporting properly to PingAccess, you can begin the upgrade process on additional engines.

### Add the engine to the load balancer configuration

1. To add the engine to the load balancer configuration, simply reverse the steps you took in [Remove the engine from the load balancer configuration](#) on page 107 to remove the engine.
2. Restart the load balancer.

Repeat the [Step 3: Upgrade engines](#) on page 106 process until each engine has been upgraded. When all engines have been upgraded, added to the load balancer configuration, and are reporting to PingAccess, you can move on to the final step, [Enable key rolling](#), to complete the zero downtime upgrade process.

### Step 4: Enable key rolling

In this step, you will resume key rolling. Note that there are different procedures at this stage depending if your source version is [PingAccess 5.0](#) or an [earlier version of PingAccess](#).

#### Source version of PingAccess 5.0 and higher

1. Navigate to **Settings > Access > Identity Mappings**.
2. In the **Auth Token Management** section, select **Key Roll Enabled**.
3. Click **Save**.
4. Navigate to **Settings > Access > Web Sessions**.
5. In the **Web Session Management** section, select **Key Roll Enabled**.
6. Click **Save**.

#### Source is an earlier version of PingAccess

1. Navigate to **Settings > Access > Identity Mappings**.
2. In the **Auth Token Management** section, specify a **Key Roll Interval** of your choosing. The default value is 24 (1 day).
3. Click **Save**.
4. Navigate to **Settings > Access > Web Sessions**.

5. In the **Web Session Management** section, specify a **Key Roll interval** of your choosing. The default value is 24 (1 day).
6. Click **Save**.

## Recovering from a failed upgrade

The Zero Downtime Upgrade process creates a set of new folders for the upgraded installation. The pre-upgrade source installation is not affected.

To recover your PingAccess cluster in the event of a failure, you would utilize the former installation by:

1. Stopping any upgraded PingAccess instances.
2. Start the original PingAccess instance on the Admin node.
3. Import the engine definitions back into the original PingAccess instance.
4. Start the original PingAccess instances on the Engine nodes.
5. Ensure all engines are added to the load balancer configuration.

# Reference Guides

---

## API Endpoints

---

### PingAccess endpoints

These endpoints enable external applications to communicate with the PingAccess server and provide complete administrative capabilities of the product.

#### *Heartbeat endpoint*

Enables administrators to verify that the server is running.

#### *OpenID Connect endpoints*

Enable PingFederate or other token providers to interface with PingAccess using the OpenID Connect (OIDC) protocol.

#### *Authentication Token Management endpoint*

Enables protected applications to validate authentication tokens issued by a PingAccess identity mapping.

#### *OAuth endpoint*

Enables an OAuth Authorization Server to interface with PingAccess as an OAuth Resource Server.

#### *Administrative API endpoints*

Enable users to use PingAccess administrative functions. These are REST APIs that include documentation and testing tools.

**Important:** Some endpoint examples in this document include the `/pa` reserved path. This document assumes the default application reserved path has not been modified. You can modify the reserved path using the *PingAccess Admin API*. If the reserved path has been modified, update endpoint and other applicable application URLs appropriately.

#### **Heartbeat endpoint**

This page describes the endpoint used to verify that the PingAccess server is running and, depending on security settings, view details about the configuration.

You can make this call to any active PingAccess listener and on any node in a PingAccess cluster. For example, with default port configurations, a Clustered Console Replica will respond to this endpoint on port 9000, and a Clustered Engine will respond to it on port 3000.

## /pa/heartbeat.ping

This endpoint returns a short or detailed status for the target PingAccess server, based on the value of the `enable.detailed.heartbeat.response` parameter in `run.properties`. Load balancers can use this endpoint to determine the status of PingAccess.

**Info:** Begin the URL with the server name and the PingAccess runtime port number. For example:

```
https://hostname:3000/pa/heartbeat.ping.
```

If an error is returned, this indicates that the PingAccess instance associated with the endpoint is down.

If `enable.detailed.heartbeat.response` is set to `false` (the default value) and the PingAccess instance is running, the endpoint returns an HTTP 200 status and the text `OK`.

If `enable.detailed.heartbeat.response` is set to `true` and the PingAccess instance is running, a configurable status with additional details is returned. The response output format is an Apache Velocity template defined in `PA_HOME/conf/template/heartbeat.page.json`. You can modify this template to suit your needs. The following values are available:

Value	Description
<code>\$monitor.getTotalJvmMemory('bytes' 'KB' 'MB' 'GB')</code>	Returns the total memory in the JVM. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getUsedJvmMemory('bytes' 'KB' 'MB' 'GB')</code>	and the PingAccess instance is running, a configurable status with additional details is returned. Returns the used memory in the JVM. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getFreeJvmMemory('bytes' 'KB' 'MB' 'GB')</code>	Returns the free memory in the JVM. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getTotalPhysicalSystemMemory('bytes' 'KB' 'MB' 'GB')</code>	Returns the total system memory. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getTotalUsedPhysicalSystemMemory('bytes' 'KB' 'MB' 'GB')</code>	Returns the used system memory. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getTotalFreePhysicalSystemMemory('bytes' 'KB' 'MB' 'GB')</code>	Returns the free system memory. Specify 'bytes', 'KB', 'MB', or 'GB' to specify the units. 'bytes' is the default if not specified.
<code>\$monitor.getHostname()</code>	Returns the hostname for the system running PingAccess.
<code>\$monitor.getNumberOfCpus()</code>	Returns the number of CPU cores in the system.
<code>\$monitor.getCpuLoad('###.##')</code>	Returns the current CPU utilization. The parameter contains an optional format value. If the format is specified, the value returned is returned as a percentage value from 0%-100%, formatted using the <a href="#">Java DecimalFormat</a> specification. If no format value is specified, then the value returned is a real number from 0 to 1 which represents the CPU utilization percentage. For example, a format value of "###.##" will return a value similar to "56.12", but no specified format would result in the value being returned as "0.5612".

Value	Description
<code>\$monitor.getOpenClientConnections()</code>	Returns the current number of clients connected to PingAccess.
<code>\$monitor.getNumberOfVirtualHosts()</code>	Returns the current number of configured virtual hosts in PingAccess.
<code>\$monitor.getNumberOfApplications()</code>	Returns the current number of configured applications in PingAccess.
<code>\$monitor.getNumberOfSites()</code>	Returns the current number of configured sites in the PingAccess configuration database. In a clustered environment, on the engine nodes, this number will reflect the number of sites associated with applications rather than the number of configured sites that show on the admin node. For more information, see <b>Server Clustering</b> documentation. This value is not included in the default template, but can be added by the system administrator if desired.
<code>\$monitor.getLastRefreshTime('yyyy/MM/dd HH:mm:ss')</code>	Returns the time the PingAccess configuration was last refreshed. The parameter specifies the date format to use; if no value is specified, the <i>ISO 8601</i> date format is used. If the parameter is specified, the format used comes from the <i>Joda DateTimeFormat</i> specification.

The default content type for the output is `application/json`. However, you can specify a content type header using the `$monitor.setContentType()` line in the template.

If you update the `enable.detailed.heartbeat.response` value, you must restart PingAccess to make the new value take effect.

### OpenID Connect endpoints

This page describes the endpoints needed for PingFederate or another token provider to interface with PingAccess using the OpenID Connect (OIDC) protocol.

These endpoints are available on the `engine.http.port` and `agent.http.port` ports defined in `PA_HOME/conf/run.properties`.

#### `/pa/oidc/logout`

This endpoint clears the browser cookie containing the PA Token. This endpoint enables end users to trigger the removal of their own PA Cookie from the browser they are using. The user is redirected to the *Logged Out* page. You can modify the template for this page, located at `<PA_INSTALL>/conf/template/general.loggedout.page.template.html`.

**Info:** This endpoint does not retain any server-side state to denote log off. Additionally, this endpoint clears the cookie only from the requested host/domain, and the cookie may still exist in requests bound for other hosts/domains.

**Note:** If you want to log out across multiple domains, you can use the PingFederate `/idp/startSLO.ping` endpoint instead. See the [PingFederate documentation](#) for more information about this endpoint.

#### `/pa/oidc/cb`

This endpoint receives the ID Token from the token provider.

**/pa/oidc/JWKS**

This endpoint is used by the token provider's JWT Token Processor for signature verification. This endpoint must be used in conjunction with the configuration of a JWT token processor instance in the token provider. For more information on configuring a JWT in PingFederate, see the [PingFederate documentation](#).

**/pa/oidc/logout.png**

This endpoint is used by the token provider to initiate a logout from PingAccess in conjunction with the single logout functionality, terminating the PA tokens across domains.

**Authentication Token Management endpoint**

This page describes the endpoint used for Authentication Token Management.

**/pa/authtoken/JWKS**

This endpoint is used by backend sites to validate the signature of a JWT. For more information on JWT, see the [OpenID Connect 1.0 Developers Guide](#).

**OAuth endpoint**

This page describes the endpoint used by an OAuth authorization server to interface with PingAccess as an OAuth resource server.

**/pa/oauth/JWKS**

This endpoint is used by an OAuth authorization server to acquire PingAccess public keys for encryption of access tokens. The output uses the IETF JWK format for public keys.

**Administrative API endpoints**

This page describes the endpoints available for administering PingAccess.

PingAccess ships with interactive documentation for both developers and non-developers to explore the PingAccess API endpoints, view a reference of the metadata for each API, and experiment with API calls. PingAccess APIs are REST APIs that provide complete administrative capabilities of the product. They can be called from custom applications or from command line tools such as cURL.

These endpoints are only available on the `admin.port` defined in `PA_HOME/conf/run.properties` at path `/pa-admin-api/v3/api-docs/` (`https://<PA_HOME>:<PORT>/pa-admin-api/v3/api-docs/`).

**Note:** For enhanced API security, you must include `X-XSRF-Header: PingAccess` in all requests and use the `application/json` content type for PUT/POST requests.

## Clustering Reference Guide

---

### Clustering

PingAccess can be configured in a clustered environment to provide higher scalability and availability for critical services.

PingAccess clusters are made up of three types of nodes:

**Administrative Node**

Provides the administrator with a configuration interface.

**Replica Administrative Node**

Provides the administrator with the ability to recover a failed administrative node using a manual failover procedure.

**Engine Node**

Handles incoming client requests and evaluates policy decisions based on the configuration replicated from the administrative node.

Any number of engine nodes can be configured in a cluster, but only one administrative node and one replica administrative node can be configured in a cluster.

You should manage incoming traffic to the engine nodes using load balancers or other mechanisms. PingAccess clusters do not dynamically manage or load-balance request traffic to individual engine nodes.

When deployed appropriately, server clustering can facilitate high availability of critical services. Clustering can also increase performance and overall system throughput. It is important to understand, however, that availability and performance are often at opposite ends of the deployment spectrum. Thus, you may need to make some configuration tradeoffs that balance availability with performance to accommodate specific deployment goals.

Configuration information is replicated to all of the engine nodes and the replica administrative node from the administrative node. State information sharing between engine nodes is not part of a default cluster configuration. However, some environments can benefit from Runtime State Clustering, which is an optional function that lets engine nodes replicate and share some state information with each other.

The license file on the administrative node is replicated to all of the engine nodes and the replica administrative node. The engine nodes do not require a license to function, but some default templates appear differently depending on the information in the license.

**Node failure implications**

The failure of a node within a PingAccess cluster can have short-term or long-term implications, depending on the node and your network state.

**Table 1: Node issues**

<b>Node issue</b>	<b>Result</b>	<b>Recommendation</b>
Administrative node failure	The engine nodes function using stored configurations, but cannot update their configurations.	Fail over to the replica administrative node until the administrative node can be restarted.
Replica administrative node failure	The engine nodes and administrative node function normally. No failover is available in case of administrative node failure.	Restart the replica administrative node as soon as possible.
Administrative and replica node failure	The engine nodes function using stored configurations, but cannot update their configurations. No failover is available.	Restart the administrative node as soon as possible, or restart the replica administrative node and fail over.
Some engine nodes cannot reach the administrative node	Affected engine nodes function using stored configurations, if any, but cannot update their configurations. If the administrative node performs key rolling, the affected engine nodes cannot recognize the new PingAccess internal cookie.	Restore administrative node access as soon as possible.

**Cluster properties**

Use the `run.properties` and `bootstrap.properties` files to configure your environment.

In a cluster, you can configure each PingAccess node to serve as either an administrative node, a replica administrative node, or an engine node in the `run.properties` file. The `run.properties` file for the administrative node also contains server-specific configuration data.

At startup, a PingAccess engine node in a cluster checks its local configuration and then makes a call to the administrative node to check for changes. You can configure how often each engine node in a cluster checks the administrative node for changes in the engine `run.properties` file.

Configuration information is replicated to all engine nodes. By default, engines do not share runtime state. You can configure nodes for Runtime State Clustering using the `run.properties` file.

Information needed to bootstrap an engine node is stored in the `bootstrap.properties` file on each engine node.

**Table 2: bootstrap.properties**

<code>engine.admin.configuration.host</code>	Defines the host where the administrative console is available. The default is <code>localhost</code> .
<code>engine.admin.configuration.port</code>	Defines the port where the administrative console is running. The default is <code>9000</code> .
<code>engine.admin.configuration.userid</code>	Defines the name of the engine.
<code>engine.admin.configuration.keypair</code>	Defines an elliptic curve key pair that is in the JSON Web Key (JWK) format.
<code>engine.admin.configuration.bootstrap.truststore</code>	Defines the truststore, in JWK format, that is used for communication with the administrative console.

**Info:** The cache can be tuned using the EHCACHE Configuration Properties (`pa.ehcache.*`) listed in the [Configuration file reference guide](#).

### Cluster node status

Engine nodes and replica administrative nodes include a status indicator that indicates the health of the node and a **Last Updated** field that indicates the date and time of the last update. The status indicator can be green (good status), yellow (degraded status), or red (failed status).

The status is determined by using the value for `admin.polling.delay` as an interval to measure health:

<b>Green (good status):</b>	The node contacted the administrative node on the last pull request.
<b>Yellow (degraded status):</b>	The node contacted the administrative node between 2 and 10 intervals.
<b>Red (failed status):</b>	The node has either never contacted the administrative node, or it has been more than 10 intervals since the nodes communicated.

### Using multiple network interface cards to route traffic

The routing of different types of traffic over specific interfaces is a network infrastructure exercise. However, PingAccess does support the routing of traffic over multiple network interfaces since, by default, PingAccess binds to all interfaces, as specified by a `0.0.0.0` address for the following parameters in `conf/run.properties`.

```
admin.bindAddress=0.0.0.0
clusterconfig.bindAddress=0.0.0.0
```

```
engine.http.bindAddress=0.0.0.0
agent.http.bindAddress=0.0.0.0
```

You can override this setting by specifying a single bind address.

### Runtime state clustering

Runtime state clustering provides better scaling of large PingAccess deployments by allowing multiple engine nodes in the configuration to share certain information. A load balancer is placed in front of each group of nodes in order to distribute connections to the nodes.

Runtime state clustering serves three purposes:

- Providing fault-tolerance for mediated tokens if an engine node is taken offline.
- Reducing the number of STS transactions with PingFederate when the front-end load balancer does not provide a sticky session.
- Ensuring rate limits are enforced properly if the front-end load balancer does not provide a sticky session.

Runtime state clustering is not necessary in most environments. It can be beneficial in very large environments or environments using rate limiting rules or token mediation.

## Configure a PingAccess cluster

This procedure installs and configures PingAccess on each cluster node, including the administrative node, an optional replica administrative node, and one or more engine nodes. The initial node becomes the administrative node, and is used to configure the rest of the cluster.

### About this task

The configuration includes setting the `pa.operational.mode` property on each node. Do not modify this property until directed to do so.

### Steps

1. Install PingAccess on each cluster node.

**Note:** The sequence of the configuration flow is significant: host names first, then generate keys, and then configure the cluster.

2. Create a key pair for the PingAccess administrative console that uses the DNS name of the administrative node as the common name. If an administrative replica console is created, this key pair needs to either be configured with the administrative replica node defined in the Subject Alternative Names for the key pair, or the key pair needs to be configured as a wildcard certificate.

**Info:** Using an IP address as the common name or in the subject alternative names is also acceptable, as long as those values are used in the administrative node fields on the **Administrative Nodes** configuration page.

3. Go to **Settings > System > Clustering > Administrative Nodes** and define the **Primary Administrative Node** as a *host.port* pair.

The *host* must be a resolvable DNS name for the node or the node's IP address. The *port* is the TCP port PingAccess listens to for the administrative interface. The default port is 9090.

4. If a replica administrative node will be used in the cluster, perform the following steps:

- a) Define a *host.port* pair for the replica administrative node.
- b) Click **Save & Download** to download the replica administrative node configuration file.
- c) Copy the downloaded `replica1_data.zip` file to the replica administrative node.

**Note:** If a replica administrative node is added after the cluster has been deployed, it will be necessary to update the configuration for each engine node when the replica administrative node is added.

5. Go to **Settings > Security > Key Pairs** and create a new key pair to assign to the `ADMIN` listener. The key pair needs to be valid for both the administrative and replica administrative nodes.

**Tip:** If a replica administrative node is not defined during the initial cluster configuration, you might still opt to define a subject alternative name for a future replica administrative node. This avoids having to reissue the keys when adding the replica administrative node in the future.

6. Open `conf/run.properties` in an editor and change the `pa.operational.mode` value to `CLUSTERED_CONSOLE`.
7. Goto **Settings > Networking > Listeners** and assign the newly created key pair to the `CONFIG_QUERY` listener.
 

**Note:** If `clusterconfig.enabled` is set to `false` in `run.properties`, the key pair needs to be assigned to the `ADMIN` listener instead. This property is set to `false` when a cluster has been upgraded from PingAccess 3.2 or earlier.

8. Restart PingAccess on the administrative node.

Perform steps 9-11 on the replica administrative node, if one has been configured.

9. Unzip `replica1_data.zip` in the `PA_HOME` directory.
10. Open `conf/run.properties` in an editor and change the `pa.operational.mode` value to `CLUSTERED_CONSOLE_REPLICA`
11. Start PingAccess on the replica administrative node.

For each engine node, perform steps 12-17.

12. Navigate to **Settings > System > Clustering** and click **Add Engine**.
13. After defining the engine's parameters, click **Save & Download** to download the engine configuration zip file.
14. Copy `engine_name_data.zip` to the engine node.
15. On the engine node, unzip `engine_name_data.zip` in the `PA_HOME` directory.
16. On the engine node, open `conf/run.properties` in an editor and change the `pa.operational.mode` value to `CLUSTERED_ENGINE`.
17. Start PingAccess on the engine node.

## Results

Go to **Settings > System > Clustering** to check your cluster's status. If everything is configured properly, the cluster engine nodes and optional replica administrative node should show a green status icon, indicating that the cluster is operational.

You can optionally configure each node to run PingAccess as a service set to automatically run when the node is started. For more information about configuring PingAccess as a service, see the installation documentation.

## Configuring the administrative node

You can configure one PingAccess node as the administrative node.

### About this task

This procedure allows you to specify an HTTP or HTTPS proxy. If proxy configuration is defined in a properties file (`bootstrap.properties` or `run.properties`), it will take precedence over UI or API configuration.

If a proxy is configured on a replica administrative node, when failing over and before removing the `bootstrap.properties` file, the administrative node should have the same proxy configuration.

**Warning:** If you are promoting a replica administrative node to an administrative node, remove the `bootstrap.properties` file from the replica administrative node.

### Steps

1. Go to **System > Clustering > Administrative Nodes**.
2. Enter the host and port for the administrative console. The default is `localhost:9000`.
3. If applicable, specify an **HTTP Proxy** for the engine. Click **Create** to create an HTTP proxy.
4. If applicable, specify an **HTTPS Proxy** for the engine. Click **Create** to create an HTTPS proxy.
5. Click **Save**.

## Configure runtime state clustering

Runtime state clustering lets multiple engine nodes share information and runtime states. This can improve performance in large environments or environments using rate limiting rules or token mediation.

### About this task

#### Steps

1. Modify `PA_HOME/conf/run.properties` and change the `pa.cluster.interprocess.communication` value from `none` to either `tcp` or `udp`.  
Using UDP for the interprocess communication allows a multicast group to be used for this communication, which may be more efficient in large environments.
2. If TCP is used for interprocess communication, configure the `pa.cluster.tcp.discovery.initial.hosts` value to specify a list of initial hosts to contact for group discovery.
3. If UDP is used for interprocess communication, optionally configure the `pa.cluster.mcast.group.address` and `pa.cluster.mcast.group.port` values for each group of nodes.
4. Update the `pa.cluster.bind.address` with the IP address of the network interface that should handle the interprocess communication traffic for the cluster.
5. Place a load balancer in front of each group of nodes to distribute the load across the nodes.
6. Restart the engine nodes.

## Configuring the replica administrative node

You can configure one PingAccess node as a replica administrative node to provide an alternative if the administrative node fails.

### About this task

When using a replica administrative node, you must define a key pair to use for the CONFIG QUERY listener that includes both the administrative node and the replica administrative node. You can do this either by using a wildcard certificate or by defining subject alternative names in the key pair that include the replica administrative node's DNS name. If you use a replica administrative node in your configuration, configure the replica administrative node before defining the engine nodes, or the `bootstrap.properties` files generated for the engine nodes will not include information about the replica administrative node.

In addition to the configuration below, the Replica Administrative node includes a status indicator that indicates the health of the node and a read-only **Last Updated** field that indicates the date and time of the last update. The status indicator can be green (good status), yellow (degraded status), or red (failed status).

The status is determined by using the value for `admin.polling.delay` as an interval to measure health:

#### **Green (good status):**

The replica administrative node contacted the primary administrative node on the last pull request.

**Yellow (degraded status):**

The replica administrative node contacted the primary administrative node between 2 and 10 intervals.

**Red (failed status):**

The replica administrative node has either never contacted the primary administrative node, or it has been more than 10 intervals since the nodes communicated.

**Note:** If you are configuring a replica administrative node in the environment, that must be done before you configure the engines.

**Steps**

1. Go to **System > Clustering > Administrative Nodes**.
2. Configure the **Host** value. This name and port pair must match either a subject alternative name in the key pair or be considered a match for the wildcard specified if the key pair uses a wildcard in the common name.
3. If applicable, specify an **HTTP Proxy** for the engine. Click **Create** to create an HTTP proxy.
4. If applicable, specify an **HTTPS Proxy** for the engine. Click **Create** to create an HTTPS proxy.
5. Specify the **Replica Administrative Node Trusted Certificate** to use for cases where a TLS-terminating network appliance, such as a load balancer, is placed between the engines and the admin node.
6. Click **Save & Download** to download the `<replicaname>_data.zip` file for the replica administrative node. PingAccess automatically generates and downloads a public and private key pair into the `bootstrap.properties` file for the node. The **Public Key** is indicated on this screen.
7. Copy the downloaded file to the replica administrative node's `PA_HOME` directory and unzip it.
8. If the replica administrative node is running on a Linux host, execute the command `chmod 400 conf/pa.jwk`.
9. Edit `PA_HOME/conf/run.properties` on the replica administrative node and change the `pa.operational.mode` value to `CLUSTERED_CONSOLE_REPLICA`.
10. Start the replica administrative node.
11. Verify replication has completed by monitoring the `PA_HOME/log/pingaccess.log` file and looking for the message "Configuration successfully synchronized with administrative node".

**Manual fail over to the replica administrative node**

You can manually promote the replica administrative node to the administrative node if the administrative node has failed.

**About this task**

The replica administrative node is intended to be used for disaster recovery purposes. If the clustered console is recoverable, then that recovery should be used rather than failing over to the replica administrative node.

**Warning:** Only one primary administrative node should be running for the cluster at any given time.

**Steps**

1. Open `PA_HOME/conf/run.properties` in an editor.
2. Locate the `pa.operational.mode` line and change the value from `CLUSTERED_CONSOLE_REPLICA` to `CLUSTERED_CONSOLE`.

This change is detected while the node is running, and does not require a restart of the node.

## Reinstate a replica administrative node after failing over

After you have failed over to your replica administrative node, you must configure a new replica administrative node.

### About this task

After the console has been failed over to the replica, you need to set up a new replica administrative console.

### Note:

If you want to then switch back to the original console, shut down the original replica node, and fail over back to the newly created replica console. Follow these steps a second time to re-establish the original replica node.

### Steps

1. Install the new replica administrative node.
2. Change the `run.properties` value for `pa.operational.mode` to `CLUSTERED_CONSOLE_REPLICA`
3. Go to **Settings > System > Clustering > Administrative Nodes** and change the **Primary Administrative Node** hostname and port to the failed-over node.
4. Remove the **Replica Administrative Node** public key, then change the **Replica Administrative Node** hostname and port to point to the new replica node.
 

**Tip:** If your key pair does not include a wildcard, you can use the same hostname as the original console to avoid having to recreate the console key pair and the `bootstrap.properties` files for each engine.
5. Click **Save & Download** to download the bootstrap file for the replica administrative node.
6. Copy the downloaded file to the new replica administrative node's `<PA_HOME>/conf` directory, and rename it to `bootstrap.properties`.
7. Edit `PA_HOME/conf/run.properties` on the new replica administrative node and change the `pa.operational.mode` value to `CLUSTERED_CONSOLE_REPLICA`.
8. Start the new replica node.
9. Verify replication has completed by monitoring the `PA_HOME/log/pingaccess.log` file and looking for the message "Configuration successfully synchronized with administrative node".

## Configure an engine node

You can configure one or more engine nodes within your cluster to manage client requests.

### About this task

For each engine node:

### Steps

1. Click **Settings > System > Clustering**.
2. Click **Add Engine** to configure a new engine node.
3. Enter a **Name** for the engine node. Special characters and spaces are allowed.
4. Enter a **Description** of the engine node.
5. If applicable, specify an **HTTP Proxy** for the engine node. Click **Create** to create an HTTP proxy.
6. If applicable, specify an **HTTPS Proxy** for the engine node. Click **Create** to create an HTTPS proxy.
7. Specify the **Engine Trusted Certificate** to use for cases where a TLS-terminating network appliance, such as a load balancer, is placed between the engines and the administrative node.

8. Click **Save & Download** to generate and download a public and private key pair into the `<enginename>_data.zip` file for the engine. This file is prepended with the name you give the engine node. Depending on your browser configuration, you may be prompted to save the file.
9. Copy the zip file to the `PA_HOME` directory of the corresponding engine node in the cluster and unzip it. The engine uses these files to authenticate and communicate with the administrative console.
 

**Info:** You can generate a new key for an engine node at any time by clicking **Save & Download** and unzipping the `<enginename>_data.zip` archive on the engine node to replace the files with a new set of configuration files. When that engine node starts up and begins using the new files, PingAccess deletes the old key.
10. On Linux engine nodes, change the permissions on the extracted `pa.jwk` to mode 400 by executing the command `chmod 400 conf/pa.jwk` after extracting the zip file.
11. Start each engine node.

## Editing an engine node

You can edit the name and description of an engine node within your cluster, and download a new public key if necessary.

### Steps

1. Go to **System > Clustering**.
2. Expand the node you want to edit, then click .
3. Edit the node **Name** or **Description**, as appropriate.
4. If a new public key is needed, click **Save & Download**.
5. If a new public key is not needed, click **Save**.

## Revoke access from an engine node

You can remove an engine node's access to the administrative node.

### About this task

If an engine node has been compromised, you can delete its public keys from the administrative node to prevent it from accessing the administrative node. You can recreate these keys after you have recovered the engine node.

### Steps

1. Go to **Settings > System > Clustering**.
2. Expand the engine node you wish to remove from the cluster and edit it.
3. Click **Delete** under the **Public Keys** heading to revoke the engine node's access to the administrative node.
 

**Info:** You can use the **Save & Download** button to create a new key for the engine. See [Configure an engine node](#) on page 121 for more information.
4. Click **Save**.

## Removing an engine node

You can remove an engine node from the cluster.

### Steps

1. Go to **System > Clustering**.

2. Expand the engine node you want to delete and click to permanently remove all references to the node from the cluster.
3. Click **Delete** in the confirmation window.

## Configuration File Reference Guide

---

### Configuration file reference

This document provides a reference to configurable parameters used by PingAccess at runtime. These parameters are configured in the `run.properties` file located at `<PA_HOME>/conf/`.

**Note:** Changes made to the `run.properties` file will take effect after PingAccess is restarted.

**Tip:** When storing passwords in `run.properties`, we strongly recommend you obfuscate them using the `obfuscate.bat` or `obfuscate.sh` utility to mask the password value. This utility is located in the `PA_HOME/bin` folder.

#### **account.locking.max.consecutive.failures**

Defines the maximum number of failed login attempts before locking the account when using basic authentication in the administrative UI or administrative REST APIs. The default value is 3.

#### **account.locking.max.lockout.period**

Defines, in minutes, the amount of time to lock an account out from the administrative interfaces after exceeding the `account.locking.max.consecutive.failures`. The default value is 1.

#### **admin.acceptors**

Defines the number of admin acceptor threads used to establish connections. The default value is 1.

#### **admin.auth**

Overrides the administrator authentication method. For example, if SSO Authentication is enabled and is somehow misconfigured, this property can be used to bypass the database configuration and force the use of Basic Authentication. Default value is `default`.

#### **admin.backlog**

Defines the maximum queue length for incoming admin connection indications. The default value is 512.

#### **admin.bindAddress**

Defines the IP address that `admin.port` will bind to. This is typically required on multihomed servers having multiple IP addresses. The default value of `0.0.0.0` means that the port will bind to all of the server's IP addresses.

#### **admin.header.Strict-Transport-Security**

Sets the parameters for the Strict-Transport-Security response header sent to the browser when an administrator is interacting with the Admin UI.

#### **admin.header.X-Content-Type-Options**

Sets the parameters for the X-Content-Type-Options response header sent to the browser when an admin is interacting with the Admin UI.

#### **admin.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options HTTP response header sent to the browser when an admin is interacting with the Admin UI.

#### **admin.header.X-XSS-Protection**

Sets the parameters for the X-XSS-Protection HTTP response header sent to the browser when an admin is interacting with the Admin UI.

#### **admin.headers**

Additional headers added to responses from the PingAccess Administrator Console and the Administrator API interface. Header values are defined using the `admin.header` prefix.

#### **admin.httptransport.coreThreadPoolSize**

Defines the number of threads to keep in the admin transport pool, even if they are idle. The default value is 5.

#### **admin.httptransport.ioThreads**

Defines the number of I/O threads for the admin host. A value of 0 is used to denote that PingAccess should automatically calculate the appropriate number of I/O threads for the host. The default value is 0.

#### **admin.httptransport.maxThreadPoolSize**

Defines the maximum number of threads for the admin transport pool. The default value is -1, which denotes no limit.

#### **admin.httptransport.socketTimeout**

Defines, in milliseconds, the admin socket timeout. The default value is 30000.

#### **admin.max.request.bodylength**

Defines, in megabytes, the maximum body length for a request to the administrative API endpoint. The default value is 15.

#### **admin.polling.delay**

Defines, in milliseconds, how long after the initial query to the administrative console that the replica administrative node begins querying for configuration information. The default is every 2000 milliseconds.

#### **admin.polling.initialdelay**

Defines, in milliseconds, how long after the replica administrative node starts up before it begins to poll the administrative console for configuration information. The default is 500.

#### **admin.port**

Defines the TCP port on which the PingAccess administrative console runs. Default is 9000.

#### **admin.reuseAddress**

When enabled, allows a process to bind to a port which remains in a TIME\_WAIT state for the admin transport. The default value is `true`.

#### **admin.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with administrative HTTPS ports.

#### **admin.ssl.protocols**

Defines the protocols for use with administrative HTTPS ports.

#### **admin.ui.max.sessions**

Defines the maximum number of sessions for the admin UI when admin SLO is not enabled.

#### **agent.assets.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options HTTP response header sent to the browser via the agent when responding to a request for an asset used by a PingAccess template.

#### **agent.assets.headers**

Additional headers added to responses from PingAccess Agents. Header values are defined using the `agent.assets.header` prefix.

**agent.authz.header.required**

Defines whether PingAccess server should authenticate agent requests using agent name and shared secret in the `vnd-pi-authz` header. Default value is `true`. Setting this to `false` is useful for POCs and/or debugging.

**agent.cache.invalidated.response.duration**

Defines the duration in seconds that application configuration changes are sent by PingAccess server to agents using the `vnd-pi-cache-invalidated` header in agent responses for the changed application. Default value is `900`.

**agent.default.token.cache.ttl**

Defines, in seconds, the time to live for cached agent tokens.

**agent.error.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options HTTP response header sent to the browser via the agent when responding with a PingAccess error template.

**agent.error.headers**

Additional headers added to error responses from PingAccess Agents. Header values are defined using the `agent.error.header` prefix.

**agent.http.backlog**

Defines the maximum queue length for incoming admin connection indications. The default value is `512`.

**agent.http.bindAddress**

Defines the address from which an engine listens for agent requests.

**agent.http.enabled**

Defines whether a `STANDALONE` or `CLUSTERED_ENGINE` node listens for agent requests on the port defined by the `agent.http.port` setting. Default is `true`.

**agent.http.port**

Defines the TCP port on which the engine listens for agent requests. Default is `3030`.

**agent.http.reuseAddress**

When enabled, allows a process to bind to a port which remains in a `TIME_WAIT` state for the agent transport. The default value is `true`.

**agent.http.secure**

Defines whether the engine is using HTTPS for agent requests. Default is `true`.

**agent.httptransport.coreThreadPoolSize**

Defines the number of threads to keep in the agent transport pool, even if they are idle. The default value is `5`.

**agent.httptransport.ioThreads**

Defines the number of I/O threads for the agent host. A value of `0` is used to denote that PingAccess should automatically calculate the appropriate number of I/O threads for the host. The default value is `0`.

**agent.httptransport.maxThreadPoolSize**

Defines the maximum number of threads for the agent transport pool. The default value is `-1`, which denotes no limit.

**agent.httptransport.socketTimeout**

Defines, in milliseconds, the agent socket timeout. The default value is `30000`.

**agent.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with agent HTTPS ports.

**agent.ssl.protocols**

Defines the protocols used for communication with agent HTTPS ports.

**as.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with authorization server HTTPS ports.

**as.ssl.protocols**

Defines the protocols used for communication with authorization server HTTPS ports.

**client.ioThreads**

Defines the number of threads for client connections to backend sites. A value of 0 means there is no limit. The default value is 0.

**clusterconfig.acceptors**

Defines the number of cluster configuration acceptor threads used to establish connections. The default value is 1.

**clusterconfig.backlog**

Defines the maximum queue length for incoming cluster configuration connection indications. The default value is 512.

**clusterconfig.bindAddress**

Defines the optional address used for cluster configuration.

**clusterconfig.enabled**

When enabled, uses the cluster configuration port for cluster replication. When disabled, the admin port is used for cluster configuration replication. The default value is `true`.

**Note:** This parameter is set to `false` by the PingAccess Upgrade Utility after a PingAccess cluster is upgraded from a version earlier than 4.0.

**clusterconfig.httptransport.coreThreadPoolSize**

Defines the number of threads to keep in the cluster configuration transport pool, even if they are idle. The default value is 5.

**clusterconfig.httptransport.ioThreads**

Defines the number of I/O threads for the cluster configuration host. A value of 0 is used to denote that PingAccess should automatically calculate the appropriate number of I/O threads for the host. The default value is 0.

**clusterconfig.httptransport.maxThreadPoolSize**

Defines the maximum number of threads for the cluster configuration transport pool. The default value is `-1`, which denotes no limit.

**clusterconfig.httptransport.socketTimeout**

Defines, in milliseconds, the cluster configuration socket timeout. The default value is 30000.

**clusterconfig.port**

Defines the optional port used for cluster configuration.

**clusterconfig.reuseAddress**

When enabled, allows a process to bind to a port which remains in a `TIME_WAIT` state for the cluster configuration transport. The default value is `true`.

**clusterconfig.secure**

When enabled, enables SSL communications for the cluster configuration port. The default value is `true`.

#### **clusterconfig.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with HTTPS ports in a clustered configuration.

#### **clusterconfig.ssl.protocols**

Defines the protocols used for communication with HTTPS ports in a clustered configuration.

#### **enable.detailed.heartbeat.response**

When enabled, this setting enables a customizable heartbeat response to be returned. When disabled, the heartbeat endpoint returns a `200 OK` response. The default value is `false`.

#### **engine.admin.configuration.audience**

Defines the audience used for cluster authentication. This property must be set to the same value on all nodes in a PingAccess cluster. The default value is `PingAccessAdminServer`.

#### **engine.assets.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options HTTP response header sent to the browser via the engine when responding to a request for an asset used by a PingAccess template.

#### **engine.assets.headers**

Additional headers added to responses from the PingAccess Engine. Header values are defined using the `engine.assets.header` prefix.

#### **engine.error.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options HTTP response header sent to the browser via the engine when responding with a PingAccess error template.

#### **engine.error.headers**

Additional headers added to error responses from the PingAccess Engine. Header values are defined using the `engine.error.header` prefix.

#### **engine.http.acceptors**

Defines the number of engine acceptor threads used to establish connections. The default value is `1`.

#### **engine.http.backlog**

Defines the maximum queue length for incoming engine connection indications. The default value is `512`.

#### **engine.http.bindAddress**

Defines the address for an engine in a clustered environment.

#### **engine.http.enabled**

Defines whether a `STANDALONE` or `CLUSTERED_ENGINE` node listens for requests on the ports defined by the Engine Listeners. Default is `true`.

#### **engine.http.reuseAddress**

When enabled, allows a process to bind to a port which remains in a `TIME_WAIT` state for the engine transport. The default value is `true`.

#### **engine.httptransport.coreThreadPoolSize**

Defines the number of threads to keep in the engine transport pool, even if they are idle. The default value is `5`.

#### **engine.httptransport.ioThreads**

Defines the number of I/O threads for the engine host. A value of 0 is used to denote that PingAccess should automatically calculate the appropriate number of I/O threads for the host. The default value is 0.

#### **engine.httptransport.maxThreadPoolSize**

Defines the maximum number of threads for the engine transport pool. The default value is -1, which denotes no limit.

#### **engine.httptransport.socketTimeout**

Defines, in milliseconds, the engine socket timeout. The default value is 30000.

#### **engine.polling.delay**

Defines, in milliseconds, how long after the initial query to the administrative console that the engine begins querying for configuration information. The default is every 2000 milliseconds.

#### **engine.polling.initialdelay**

Defines, in milliseconds, how long after the engine starts up before it begins to poll the administrative console for configuration information. The default is 500.

#### **engine.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with engine HTTPS ports.

#### **engine.ssl.protocols**

Defines the protocols used with engine HTTPS ports.

#### **engine.websocket.maxConnections**

Sets the maximum number of allowed web socket connections. Default is -1 (unlimited).

#### **pa.admin.test.connections**

A boolean property that allows the PingAccess admin UI to make HTTP calls to validate that it can reach PingFederate and sites when the user configures them.

#### **pa.admin.user.password.error.message**

Defines the message returned when password complexity is not satisfied. The default value is `Password must be at least 8 characters in length, contain one upper-case letter, one lower-case letter and one digit..`

#### **pa.admin.user.password.regex**

Defines the regex that controls password complexity for the Administration Console. The default value is

```
((?=.*\\d)(?=.*[a-z])(?=.*[A-Z]).{8,20})
```

#### **pa.auditing.unknown.resource**

When set to `true`, this setting causes PingAccess to audit requests for resources that are requested but not mapped to an Application or Resource. This setting can be used to help troubleshoot resource definition issues. The default is `false`.

#### **pa.backup.filesToKeep**

Defines the number of backup files to preserve when the Administrator authenticates to PingAccess. The default value is 25. A value of 0 disables the creation of backup files.

**Note:** Disabling the creation of backup files can speed up the login process in large environments. If you disable the creation of backup files, use the administrative API backup endpoint to create regular backups.

#### **pa.cluster.auth.pwd**

Sets the key that each engine in the cluster must use to authenticate when joining the group. This prevents unauthorized engines from joining a cluster. This key should be

treated as a strong key rather than as a human-readable password value. (Values: any string or blank)

**Important:** If `pa.cluster.encrypt` is true, `pa.cluster.auth.pwd` must not be blank.

#### **pa.cluster.bind.address**

Defines the IP address to which you bind the TCP or UDP listener. The default is `127.0.0.1`.

#### **pa.cluster.bind.port**

The port associated with the bind-address property above. The default is `7610`. Whether this is a TCP or UDP port depends on the value configured for the `pa.cluster.interprocess.communication` property (see above).

#### **pa.cluster.encrypt**

Indicates whether to encrypt network traffic sent between engines in a cluster. (Values: `true` or `false` [default])

**Important:** If `pa.cluster.encrypt` is true, `pa.cluster.auth.pwd` must not be blank.

#### **pa.cluster.failure.detection.bind.port**

Indicates the bind port of a server socket that is opened on the given engine and used by other engines as part of one of the cluster's failure-detection mechanisms. This port is bound to the address determined by `pa.cluster.bind.address`. The default is `7710`. Whether this is a TCP or UDP port depends on the value configured for the `pa.cluster.interprocess.communication` property (see above).

#### **pa.cluster.interprocess.communication**

Defines how the JGroups cluster communicates. `none` (the default): Indicates that no communication is configured between servers in the cluster. `udp`: Indicates that the cluster uses Multicast communications to send and receive information to and from multiple servers at once. `tcp`: Indicates that the cluster uses Unicast communications to send and receive information to and from individual servers one at a time.

#### **pa.cluster.mcast.group.address**

Defines the IP address shared among engines in the same cluster for UDP multicast communication; required when the interprocess communication mode is set to `udp`. (Range: `224.0.0.0` to `239.255.255.255`; note that some addresses in this range are reserved for other purposes.) This property is not used for TCP. All engines in a cluster must use the same address for this property and the port property below. The default value is `239.16.96.69`.

#### **pa.cluster.mcast.group.port**

Defines the UDP port associated with the `pa.cluster.mcast.group.address` property above. The default value is `7611`.

#### **pa.cluster.serverstate.replicationIntervalMilliseconds**

Defines, in milliseconds, how often Rate Limiting metadata is replicated within a subcluster. The default value is `1000`.

#### **pa.cluster.serverstate.staleEntryEvictionIntervalSeconds**

Defines, in seconds, how often a PingAccess engine scans the Rate Limiting metadata to evaluate metadata to be removed from the cache, based on the `pa.cluster.serverstate.timeToIdleSeconds` value. The default value is `60`.

#### **pa.cluster.serverstate.timeToIdleSeconds**

Defines, in seconds, how long metadata for the Rate Limiting rule is maintained by a PingAccess Engine after its last use. The default value is `86400`.

**pa.cluster.tcp.discovery.initial.hosts**

Designates the initial hosts to be contacted for group membership information when discovering and joining the group; required when the interprocess communication mode is set to `tcp`. The value is a comma-separated list of host names (or IP addresses) and ports. For example, `127.0.0.1[7602]`.

**pa.default.availability.ondemand.connectTimeout**

Defines, in milliseconds, the amount of time to wait before trying to connect to the remote host. The default is `10000`.

**pa.default.availability.ondemand.failedRetryTimeout**

Defines, in seconds, the amount of time to wait before retrying a failed host. The default is `60`.

**pa.default.availability.ondemand.maxRetries**

Defines the maximum number of retries before marking the target system down. The default is `2`.

**pa.default.availability.ondemand.pooledConnectionTimeout**

Defines, in milliseconds, the amount of time to wait before timing out the request for a pooled connection to the target site. The default is `-1`.

**pa.default.availability.ondemand.readTimeout**

Defines, in milliseconds, the amount of time to wait before timing out the read response for a target site. The default is `-1`.

**pa.default.availability.ondemand.retryDelay**

Defines, in milliseconds, the amount of time to wait after a timeout before retrying the host. The default is `250`.

**pa.default.contentRewrite.buffer.default**

Defines, in bytes, the default buffer size when using a Rewrite Content rule to do a search and replace of content. The default value is `2048`.

**pa.default.contentRewrite.buffer.min**

Defines, in bytes, the minimum buffer size used when using a Rewrite content rule. The default value is `1024`.

**pa.default.limitRequestLine**

Defines the maximum number of bytes to read from the request line. The default value is `8192`.

**pa.default.maxConnectionsPerSite**

Defines the maximum number of connections PingAccess will open to the PingFederate Admin or Engine. A value of `-1` means there is no limit. The default is `-1`.

**pa.default.maxHeaderCount**

Defines the maximum number of headers to read from a request. The default value is `100`.

**pa.default.maxHttpRequestSize**

Defines the maximum number of bytes to read when reading headers. The default value is `8192`.

**pa.default.maxRequestBodySize**

Defines the maximum number of bytes to read from a request body. The default value is `204800`.

**pa.default.session.cookie.attributes.httponly**

Defines the default setting for the **HTTP-Only Cookie** setting for newly-created web sessions. The default value is `true`.

**pa.default.session.cookie.attributes.secure**

Defines the default setting for the **Secure Cookie** setting for newly-created web sessions. The default value is `true`.

**pa.default.session.cookie.size.threshold**

Defines, in bytes, the default maximum session cookie size. The default value is 4093.

**pa.ehcache.AuthTokenCache.maxEntriesLocalHeap**

Defines the maximum size of the JWT identity mapping token cache used when sending tokens to a protected site. Default is 10000.

**pa.ehcache.PATokenValidationCache.maxEntriesLocalHeap**

Defines the maximum number of entries in the local heap for decryption of signed or encrypted PingAccess tokens. The default is 10000.

**pa.ehcache.PATokenValidationCache.timeToldleSeconds**

Defines, in seconds, the time an entry in the token validation cache can be idle before it is expired. The default is 120 seconds.

**pa.ehcache.PATokenValidationCache.timeToLiveSeconds**

Defines, in seconds, the maximum time an entry can be in the token validation cache. The default is 300 seconds.

**pa.ehcache.PAWamUserAttributesCache.maxEntriesLocalHeap**

Defines the maximum number of entries in the local heap for the PA WAM user attribute cache. The default is 10000.

**pa.ehcache.PAWamUserAttributesCache.timeToldleSeconds**

Defines, in seconds, the time an entry in the PA WAM user attribute cache can be idle before it is expired. The default is 120 seconds.

**pa.ehcache.PAWamUserAttributesCache.timeToLiveSeconds**

Defines, in seconds, the maximum time an entry can be in the PA WAM user attribute cache. The default is 300 seconds.

**pa.ehcache.PFSessionValidationCache.maxEntriesLocalHeap**

Defines the maximum number of entries in the local heap for the session validation cache. The default is 10000.

**pa.ehcache.PFSessionValidationCache.timeToldleSeconds**

Defines, in seconds, the time an entry in the session validation cache can be idle before it is expired. The default is 120 seconds.

**pa.ehcache.PFSessionValidationCache.timeToLiveSeconds**

Defines, in seconds, the maximum time an entry can be in the session validation cache. The default is 300 seconds.

**pa.ehcache.PingFederateReferenceTokenCache.maxEntriesLocalHeap**

Defines the maximum number of entries in the local heap for OAuth tokens. The default is 10000.

**pa.ehcache.ServiceTokenCache.maxEntriesLocalHeap**

Defines the maximum number of entries in the local heap for token mediation. The default is 10000.

**pa.ehcache.ServiceTokenCache.timeToldleSeconds**

Defines, in seconds, the time an entry in the token mediation cache can be idle before it is expired. The default is 1800 seconds.

**pa.ehcache.ServiceTokenCache.timeToLiveSeconds**

Defines, in seconds, the maximum time an entry can be in the token mediation cache. The default is 14400 seconds.

#### **pa.ehcache.SessionStateCache.maxEntriesLocalHeap**

Defines the maximum size of the identity attribute entry cache when the user's attributes are stored on the server rather than as a cookie. Default is 10000.

#### **pa.interceptors.relativepath.decode.count**

Number of times the URL is decoded to check for path traversal characters. The default is 3.

#### **pa.interceptors.relativepath.decode.regex**

Defines the accepted URL regex pattern that administrators can customize based on their needs. The default value is: Defines the regular expression to use when checking for a valid path in an incoming request. The default value is

```
[\\p{Po}\\p{N}\\p{Z}\\p{L}\\p{M}\\p{Zs}\\. /_\\-\\~()\\{\\}\\[\\ \\]]*
```

**Note:** This value is double-escaped as required by the `java.util.regex.Pattern` Java class.

#### **pa.interceptors.relativepath.strict**

When this property is set to `true`, the incoming URL is matched with the whitelist pattern defined in `pa.interceptors.relativepath.decode.regex`. All other request URLs are rejected. The default value is `false`.

#### **pa.jdbc.filepassword**

Defines the password used to encrypt the PingAccess configuration database. Default is `2Access`.

#### **pa.jdbc.password**

Defines the password for the database user of the PingAccess configuration database. Default is `2Access`.

#### **pa.jdbc.username**

Defines the username for accessing the PingAccess configuration database. Default is `sa`.

#### **pa.keystore.pw**

Defines the password for the `$JAVA_HOME/lib/security/cacerts` keystore.

#### **pa.localization.missing.message.placeholder**

Defines the message used when an error message is unresolvable. An error will be logged.

#### **pa.localization.resource.bundle.cache.enable**

When set to `false`, allows language files in `/conf/localization` to be added or modified. When `true`, enables caching of language files and properties.

#### **pa.oidc.logout.redirect**

A boolean property that defines whether or not to redirect the user to the token provider on logout. If `true`, the user is redirected to the token provider.

#### **pa.oidc.logout.redirectURI**

The URI that a user gets sent to when they log out.

#### **pa.oidc.post.preservation.encrypt**

When enabled, POST data preserved through a redirection to PingFederate for authentication is encrypted on the client to be used after the authentication is successful. The default value is `false`.

**pa.oidc.post.preservation.maxRequestBodySize**

Defines, in bytes, the maximum size of the post body for POST preservation. The default value is 8192.

**pa.oidc.post.preservation.paramsAttributeName**

Used to store the encoded or encrypted POST payload in the browser session storage during POST preservation.

**pa.operational.mode**

Controls the operational mode of the PingAccess server in a cluster. Valid values are:

- **STANDALONE** - Use this value for a standalone (unclustered) PingAccess instance that runs both the administrative console and the engine. This is the default.
- **CLUSTERED\_CONSOLE** - Use this value for the server instance you want to use as the administrative console server.

**Info:** Only one engine in a cluster can run the administrative console.

- **CLUSTERED\_CONSOLE\_REPLICA** - Use this value for the server instance you want to use as the backup administrative console server.
- **CLUSTERED\_ENGINE** - Use this value to indicate a server engine.

**Note:**

Define the following Engine and Admin properties depending on what operational mode an engine is using.

- Define all of the following Engine and Admin properties when `pa.operational.mode` is set to `STANDALONE`.
- Define only the Admin properties when using `CLUSTERED_CONSOLE` or `CLUSTERED_CONSOLE_REPLICA` mode.
- Define only the Engine properties when using `CLUSTERED_ENGINE` mode.

**pa.uri.strict**

When enabled, this setting requires the raw input URI be in strict compliance with the URI spec implemented by `java.net.URI` when generating URIs. The default value is `false`.

**pf.api.keepAliveTimeout**

Defines, in milliseconds, the keep alive timeout for the PingFederate API. The default value is 30000.

**pf.api.maxConnections**

Defines the maximum number of connections PingAccess will establish to the PingFederate API endpoint. A value of `-1` means there is no limit. The default value is `-1`.

**pf.api.maxRetries**

Defines the maximum number of retries PingAccess attempts to make to the PingFederate server before declaring the server unavailable. The default value is 0.

**pf.api.readTimeout**

Defines, in milliseconds, how long the API will wait for responses from PingFederate when making calls to the PingFederate Admin API. The default value is `-1`.

**pf.api.socketTimeout**

Defines, in milliseconds, the socket timeout for the PingFederate API endpoint. The default value is 5000.

**pf.redirect.header.X-Frame-Options**

Sets the parameters for the X-Frame-Options value that is sent when the user is redirected to PingFederate to authenticate.

**pf.redirect.headers**

Additional headers added to the redirection response that sends the client to PingFederate for authentication. Header values are defined using the `pf.redirect.header` prefix.

#### **pf.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with PingFederate HTTPS ports.

#### **pf.ssl.protocols**

Defines the protocols used for communication with PingFederate HTTPS ports.

#### **provider.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with Provider HTTPS ports.

#### **provider.ssl.protocols**

Defines the protocols used for communication with Provider HTTPS ports.

#### **rule.error.headers**

Additional headers added to responses that result from policy rule results. Header values are defined using the `rule.error.header` prefix.

#### **site.ssl.ciphers**

Defines the type of cryptographic ciphers available for use with Site HTTPS ports.

#### **site.ssl.protocols**

Defines the protocols used for communication with Site HTTPS ports.

#### **tls.default.cipherSuites**

Defines the default set of ciphers used for HTTPS communication.

**Note:** Legacy browsers may require the addition of SHA1-based ciphers to negotiate a cipher suite with the server. In this case, add the following ciphers to the `run.properties` file and restart PingAccess:

- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA

#### **tls.default.protocols**

Defines the default protocols used for HTTPS communication.

## **Deployment Reference Guide**

---

### **PingAccess deployment guide**

There are many topics to consider when deciding how PingAccess fits into your existing network, from determining the deployment architecture required for your use case and whether high-availability options are required.

This section provides information to help you make the right decisions for your environment.

### **Use cases and deployment architecture**

There are many options for deploying PingAccess in your network environment depending on your needs and infrastructure capabilities.

For example, you can design a deployment that supports mobile and API access management, Web access management, or auditing and proxying. For each of these environments, you can choose a stand-alone deployment for proof of concept or deploy multiple PingAccess servers in a cluster configuration for high availability, server redundancy, and failover recovery.

You have a choice between using PingAccess as a Gateway or using a PingAccess Agent plugin on the web server. In a gateway deployment, all client requests first go through PingAccess and are checked for authorization before they are forwarded to the target site. In an agent deployment, client requests go directly to the web server serving up the target site, where they are intercepted by the Agent plugin and checked for authorization before they are forwarded to the target resource. The same access control checks are performed by the PingAccess Policy Server in both cases and only properly authorized client requests are allowed to reach the target assets. The difference is that in a gateway deployment client requests are rerouted through PingAccess Gateway, while in an agent deployment they continue to be routed directly to the target site, where PingAccess Agent is deployed to intercept them.

PingAccess Agent makes a separate access control request to PingAccess Policy Server using the PingAccess Agent Protocol (PAAP). The *agent request* contains just the relevant parts of the client request so that PingAccess Policy Server can make the access control decision and respond with instructions to the agent regarding any modifications to the original client request that the agent should perform prior to forwarding the request. For example, the agent may add headers and tokens required by the target resource. Under the PingAccess Policy Server's control, the agent may perform a certain amount of caching of information in order to minimize the overhead of contacting the PingAccess Policy Server, thus minimizing response time.

In both gateway and agent deployment the response from the target resource is processed on the way to the original client. In an agent deployment, the amount of processing is more limited than in a gateway deployment. The agent does not make another request to the Policy Server, so response processing is based on the initial agent response. Consequently, the agent is not able to apply the request processing rules available to the gateway.

When designing a deployment architecture, many requirements and components must be identified for a successful implementation. Proper network configuration of routers/firewalls and DNS ensure that all traffic is routed through PingAccess for the Resources it is protecting and that alternative paths (for example, backdoors) are not available.

The following sections provide specific use cases and deployment architecture requirements to assist with designing and implementing your PingAccess environment.

### **Deploy for Gateway Web Access Management**

A PingAccess Web access management (WAM) deployment enables an organization to quickly set up an environment that provides a secure method of managing access rights to Web-based applications while integrating with existing identity management infrastructure.

With growing numbers of internal and external users, and more and more enterprise resources available online, it is important to ensure that qualified users can access only those applications to which they have permission. A WAM environment provides authentication and policy-based access management while integrating with existing infrastructure.

Deployed at the perimeter of a protected network between browsers and protected Web-based applications, PingAccess Gateway performs the following actions:

- Receives inbound calls requesting access to Web applications. Web Session protected requests contain a previously-obtained PA token in a cookie derived from the user's profile during an OpenID Connect based login at PingFederate.
- Evaluates application and resource-level policies and validates the tokens in conjunction with an OpenID Connect Policy configured within PingFederate.
- Acquires the appropriate target security token (Site Authenticators) from the PingFederate STS or from a cache (including attributes and authorized scopes) should a Web application require identity mediation.
- Makes authorized requests to the sites where the Web applications reside and responses are received and processed.
- Relays the responses on to the browsers.

The following sections describe sample Proof of Concept and Production architectures for a WAM use case deployment.

- [WAM Gateway POC Deployment Architecture](#)
- [WAM Gateway Production Deployment Architecture](#)

### Deploy for Agent Web Access Management

A PingAccess Web access management (WAM) agent deployment enables an organization to quickly set up an environment that provides a secure method of managing access rights to Web-based applications while integrating with existing identity management infrastructure and minimal network configuration changes.

With growing numbers of internal and external users, and more and more enterprise resources available online, it is important to ensure that qualified users can access only those applications to which they have permission. A WAM environment provides authentication and policy-based access management while integrating with existing infrastructure.

The PingAccess Agent plugin is installed on the Web server hosting the protected Web-based applications and configured to communicate with PingAccess Server also deployed on the network. When the agent intercepts a client request to a protected Web application resource it performs the following actions:

- Intercepts inbound requests to Web applications.
- Sends agent requests to the PingAccess Policy Server sending along relevant request information needed by Policy Server.
- Receives agent responses from Policy Server and follows the instructions from Policy Server, modifies the request as specified, and allows the request to proceed to the target resource.
- Intercepts responses from the application and modifies response headers as instructed in the initial agent request to Policy Server.
- Relays responses on to the browsers.

The PingAccess Policy Server listens for agent requests and performs the following actions:

- Evaluates application and resource-level policies and validates the tokens in conjunction with an OpenID Connect Policy configured within PingFederate
- Acquires the appropriate HTTP request header configuration from the associated Identity Mappings.
- Sends an agent response with instructions on whether to allow the request and how to modify the client request headers.

The following sections describe sample Proof of Concept and Production architectures for a WAM use case deployment.

- [WAM Agent POC Deployment Architecture](#)
- [WAM Agent Production Deployment Architecture](#)

### Deploy for Gateway API Access Management

A PingAccess API access management deployment enables an organization to quickly set up an environment that provides a secure method of controlling access to APIs while integrating with existing identity management infrastructure.

Pressure from an ever-expanding mobile device and API economy can lead developers to hastily design and expose APIs outside the network perimeter. Standardized API access management leads to a more consistent, centrally-controlled model that ensures existing infrastructure and security policies are followed, thereby safeguarding an organization's assets.

PingAccess Gateway sits at the perimeter of a protected network between mobile, in-browser, or server-based client applications and protected APIs and performs the following actions:

- Receives inbound API calls requesting protected applications. OAuth-protected API calls contain previously-obtained access tokens retrieved from PingFederate acting as an OAuth Authorization Server.
- Evaluates application and resource-level policies and validates access tokens in conjunction with PingFederate.

- Acquires the appropriate target site security token (Site Authenticators) from the PingFederate STS or from a cache (including attributes and authorized scopes) should an API require identity mediation.
- Makes authorized requests to the APIs and responses are received and processed.
- Relays the responses on to the clients.

The following sections describe sample Proof of Concept and Production architectures for an API access management use case deployment.

- [API Access Management POC Deployment Architecture](#)
- [API Access Management Production Deployment Architecture](#)

### Deploy for auditing and proxying

A PingAccess deployment for auditing and proxying enables an organization to quickly set up an environment that provides a secure method of controlling access to back-end sites.

With growing numbers of internal and external users, it is important to know which users are accessing applications, from where and when they are accessing them, and ensuring that they are correctly accessing only those applications to which they have permission. A standardized auditing/proxying deployment provides a centrally-controlled model that ensures existing infrastructure and security policies are followed, thereby safeguarding an organization's assets.

Sitting at the perimeter of a protected network between mobile, in-browser, or server-based client applications and back-end Sites, PingAccess performs the following actions:

- Receives inbound calls requesting access to protected back-end Sites.
- Audits the request and then makes authorized requests to the back-end Sites.
- Receives and processes responses and relays them on to the clients.

The following sections describe sample Proof of Concept and Production architectures for an auditing/proxying use case deployment.

- [Audit and Proxy POC Deployment Architecture](#)
- [Audit and Proxy Production Deployment Architecture](#)

## Configuration by use case

Your configuration steps will vary depending on what type of deployment you are implementing.

See the [Deployment Guide](#) for a detailed discussion of deployment considerations and best practices in designing your architecture. The following sections describe the configuration steps for the most common use cases:

- [API Access Management Gateway Deployment](#)
- [Web Access Management Agent Deployment](#)
- [Web Access Management Gateway Deployment](#)
- [Auditing and Proxying Gateway Deployment](#)

### Next steps

Once you complete the above configuration settings, your next steps are similar for all use cases:

- Configure Sites and Agents to define the target applications to be protected. Sites may need Site Authenticators to define the credentials the site expects for access control.
- Configure Applications and Resources to define the assets you wish to allow clients to access.
- Create Policies for the defined applications and resources to protect them.

### Web Access Management Gateway deployment

This table describes the important configuration options for a Web Access Management Gateway deployment.

See [Deploying for Gateway Web Access Management](#) in the [Deployment Guide](#) for specific use case information.

Step	Description
<a href="#">Configure the connection to the PingFederate.</a>	PingAccess uses PingFederate to manage web session and authentication.
<a href="#">Configure the OpenID Connect Relying Party Client for PingAccess.</a>	The client must be registered with PingFederate and the client credentials configured in PingAccess to identify PingAccess when requesting authentication for users trying to access Web applications.
<a href="#">Configure Web session details to enable protection of Web Resources.</a>	Configures settings for secure Web sessions such as timeout values, cookie parameters, and cryptographic algorithms.
<a href="#">Generate or Import Key Pairs and configure HTTP Listeners.</a>	Defines the certificates and keys used to secure access to the PingAccess administrative console and secure incoming HTTPS requests at runtime.
<a href="#">Set up your cluster for high availability.</a>	Facilitates high availability of critical services, and increases performance and overall system throughput.
<a href="#">Add trusted CA certificates.</a>	Defines trust to certificates presented during outbound secure HTTPS connections.
<a href="#">Create a trusted certificate group.</a>	Provides a trusted set of anchor certificates for use when authenticating outbound secure HTTPS connections.
<a href="#">Define virtual servers for protected resources.</a>	Allows one server to share PingAccess Resources without requiring all Sites on the server to use the same host name. If SNI is available (Java 8), specific key pairs can be assigned to virtual hosts.

### Web Access Management Agent deployment

This table describes the important configuration options for a Web Access Management Agent deployment.

See [Deploying for Agent Web Access Management](#) for specific use case information.

First, PingAccess Agent needs to be deployed using the following steps:

1. Install PA Agent on Web Server - following instruction in [PingAccess Agent for Apache Installation](#) or [PingAccess Agent for IIS Installation](#) depending on your specific Web server.
2. Define the Agents and download agent bootstrap.properties file via the download field in the Shared Secrets field.
3. Deploy the agent bootstrap.properties file to agents following instructions in [PingAccess Agent Configuration](#).

The rest of PingAccess deployment is similar to [Web Access Management Gateway Deployment](#).

Step	Description
<a href="#">Configure the connection to the PingFederate.</a>	PingAccess uses PingFederate to manage web session and authentication.

Step	Description
<a href="#">Configure the OpenID Connect Relying Party Client for PingAccess.</a>	The client must be registered with PingFederate and the client credentials configured in PingAccess to identify PingAccess when requesting authentication for users trying to access Web applications.
<a href="#">Configure Web session details to enable protection of Web Resources.</a>	Configures settings for secure Web sessions such as timeout values, cookie parameters, and cryptographic algorithms.
<a href="#">Generate or Import Key Pairs and configure HTTP Listeners.</a>	Defines the certificates and keys used to secure access to the PingAccess administrative console and secure incoming HTTPS requests at runtime.
<a href="#">Set up your cluster for high availability.</a>	Facilitates high availability of critical services, and increases performance and overall system throughput.
<a href="#">Add trusted CA certificates.</a>	Defines trust to certificates presented during outbound secure HTTPS connections.
<a href="#">Create a trusted certificate group.</a>	Provides a trusted set of anchor certificates for use when authenticating outbound secure HTTPS connections.
<a href="#">Define virtual servers for protected resources.</a>	Allows one server to share PingAccess Resources without requiring all Sites on the server to use the same host name. If SNI is available (Java 8), specific key pairs can be assigned to virtual hosts.

### API Access Management Gateway deployment

This table describes the important configuration options for deploying an API Gateway.

See [Deploying for Gateway API Access Management](#) in the [Deployment Guide](#) for specific use case information.

Step	Description
<a href="#">Configure the connection to the PingFederate OAuth Authorization Server.</a>	PingAccess uses this connection and credentials to validate incoming Access Tokens for securing API calls.
<a href="#">Configure the OpenID Connect Relying Party Client for PingAccess.</a>	The client must be registered with PingFederate and the client credentials configured in PingAccess to authenticate PingAccess when validating incoming Access Tokens.
<a href="#">Generate or Import Key Pairs and configure HTTP Listeners.</a>	Defines the certificates and keys used to secure access to the PingAccess administrative console and secure incoming HTTPS requests at runtime.
<a href="#">Set up your cluster for high availability.</a>	Facilitates high availability of critical services, and increases performance and overall system throughput.
<a href="#">Add trusted CA certificates.</a>	Defines trust to certificates presented during outbound secure HTTPS connections.

Step	Description
<a href="#">Create a trusted certificate group.</a>	Provides a trusted set of anchor certificates for use when authenticating outbound secure HTTPS connections.
<a href="#">Define virtual servers for protected applications.</a>	Allows one server to share PingAccess Resources without requiring all Sites on the server to use the same host name. If SNI is available (Java 8), specific key pairs can be assigned to virtual hosts

### Auditing and proxying Gateway deployment

This table describes the important configuration options for an auditing or proxying deployment.

See [Deploying for Auditing and Proxying](#) for specific use case information.

Step	Description
<a href="#">Generate or Import Key Pairs and configure HTTP Listeners.</a>	Defines the certificates and keys used to secure access to the PingAccess administrative console and secure incoming HTTPS requests at runtime.
<a href="#">Set up your cluster for high availability.</a>	Facilitates high availability of critical services, and increases performance and overall system throughput.
<a href="#">Add trusted CA certificates.</a>	Defines trust to certificates presented during outbound secure HTTPS connections.
<a href="#">Create a trusted certificate group.</a>	Provides a trusted set of anchor certificates for use when authenticating outbound secure HTTPS connections.
<a href="#">Define virtual servers for protected resources.</a>	Allows one server to share PingAccess Resources without requiring all Sites on the server to use the same host name.

## Web Access Management

With growing numbers of internal and external users, and more and more enterprise resources available online, it is important to ensure that qualified users can access only those resources to which they have permission. PingAccess uses Web Access Management (WAM) capabilities to allow organizations to manage access rights to Web-based resources.

WAM is a form of identity management that controls access to Web resources, providing authentication and policy-based access management. Once a user is authenticated, PingAccess applies application and resource-level policies to the request. Once policy evaluation is passed, any required identity mediation between the back-end site and the authenticated user is performed. The user is then granted access to the requested resource.

PingAccess provides two deployment architectures for Web Access Management - gateway and agent. In a gateway deployment client requests are routed to PingAccess which then forwards authorized requests to the target application. In an agent deployment, client requests are intercepted at the web server hosting the application via the PingAccess agent plugin. The agent then communicates with PingAccess Policy Server to validate access before allowing the request to proceed to the target application resource.

### Choose Between an Agent or Gateway deployment

PingAccess can be deployed using Agents, as a Gateway (or reverse proxy), or using a combination of both. Before deciding on a deployment, it is important to understand the pros and cons of each deployment scenario and determine how they impact your strategy.

## Gateway

### Pros:

- Fewer number of deployed components that require maintenance
- Independent of target application platform
- No impact on web/app server processing and performance
- Able to work with existing security token types (such as creating 3rd party WAM tokens)

### Cons:

- Requires networking changes
- Requires strategy for securing direct access to backend web/app servers (network routing or service level authentication)
- Depending on the application, may require content / request/response rewriting
- Another layer that requires HA/DR planning

## Agents

### Pros:

- No networking or server level authentication changes required
- Tight integration with web server handling requests
- Scales with application

### Cons:

- High cost of ownership when many agent instances deployed, although should be upgradable/patchable independently of PingAccess (policy) server
- Policy evaluation is cached; although it is periodically flushed/re-evaluated (for new sessions, updates to session token, etc.) it isn't quite is "real time" as proxy
- Tight dependency on web server version & platform

### Web Access Management Gateway proof of concept deployment architecture

This environment is used to emulate a WAM gateway production environment for testing purposes.

In the test environment, PingAccess can be set up with the minimum hardware requirements. This environment example does not provide high availability and is not recommended for a Production environment.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming requests for Web applications originate.
DMZ	Externally exposing segment where PingAccess is accessible to Web browsers. PingAccess is a standalone instance in this environment, serving as both a runtime and an administrative port.

Zone	Description
Protected Zone	Back-end controlled zone in which Sites hosting the protected Web applications are located. All requests to these Web applications must be designed to pass through PingAccess. PingFederate is accessible to Web browsers in this zone and is a standalone instance in this environment, serving as both a runtime and an administrative port. PingFederate requires access to identity management infrastructure in order to authenticate users (depicted by the icon in the diagram).

### Web Access Management Gateway production deployment architecture

This environment shows a WAM gateway production architecture.

There are many considerations when deploying a Production environment. For high availability and redundancy, the environment requires clustering and load-balancing. Load balancers are required as part of the networking infrastructure to achieve high availability by ensuring that requests are sent to available servers they are front-ending. Best practices in network design and security also include firewalls to ensure that only required ports and protocols are permitted across zones.

**Info:** PingAccess can provide high availability and basic load balancing for the protected web apps in the protected zone. See the Availability Profiles and Load Balancing Strategies documentation for more information.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming requests for Web applications originate.
DMZ	Externally exposing segment where PingAccess is accessible to Web browsers. A minimum of two PingAccess engine nodes will be deployed in the DMZ to achieve high availability. Depending on your scalability requirements, more nodes may be required.
Protected Zone	Back-end controlled zone in which Sites hosting the protected Web applications are located. All requests to these Web applications must be designed to pass through PingAccess. PingFederate is accessible to Web browsers in this zone and requires access to identity management infrastructure in order to authenticate users (depicted by the icon in the diagram). A minimum of two PingFederate engine nodes will be deployed in the protected zone. Administrative nodes for both PingAccess and PingFederate may be co-located on a single machine to reduce hardware requirements.

### Web Access Management Agent proof of concept deployment architecture

This environment is used to emulate a WAM agent production environment for testing purposes.

In the test environment, PingAccess can be set up with the minimum hardware requirements. This environment example does not provide high availability and is not recommended for a Production environment.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming requests for Web applications originate.
DMZ	Externally exposed segment where application Web server is accessible to Web clients. PingAccess Agent is deployed as a plugin on this Web server. The agent interacts with PingAccess Policy Server in the Protected Zone. PingFederate is deployed as a standalone instance in this environment because during user authentication clients interact with PingFederate. PingFederate requires access to Identity Management Infrastructure in order to authenticate users.
Protected Zone	Back-end controlled zone with no direct access by Web clients. PingAccess Policy Server is deployed in this zone. PingAccess interacts with PingFederate in the DMZ Zone. Identity Management Infrastructure is deployed in this zone.

### Web Access Management Agent production deployment architecture

This environment shows a WAM agent production architecture.

There are many considerations when deploying a Production environment. For high availability and redundancy, the environment requires clustering and load-balancing. Load balancers are required as part of the networking infrastructure to achieve high availability by ensuring that requests are sent to available servers they are front-ending. Best practices in network design and security also include firewalls to ensure that only required ports and protocols are permitted across zones.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming requests for Web applications originate.
DMZ	Externally exposed segment where (possibly multiple) application Web servers are accessible to Web clients. PingAccess Agent is deployed as a plugin on these Web servers. Agents interact with PingAccess Policy Server in the Protected Zone.

Zone	Description
Protected Zone	Back-end controlled zone with no direct access by Web clients. PingAccess Policy Server is deployed in a cluster in this zone with a separate administrative engine. PingFederate is also deployed in this zone in a cluster with its own separate administrative engine. PingFederate needs access to the Identity Management Infrastructure in order to authenticate users. Since during user authentication Web clients need to interact with PingFederate directly, a reverse proxy such as PingAccess Gateway is required to forward client requests through the DMZ. This aspect is not shown in the diagram.

### API Access Management proof of concept deployment architecture

This environment is used to emulate an API access management environment for testing purposes.

In the test environment, PingAccess can be set up with the minimum hardware requirements. Given these conditions, we do not recommend using this proposed architecture in a production deployment as it does not provide high availability.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming API requests originate.
DMZ	Externally exposing segment where PingAccess is accessible to API clients. PingAccess is a standalone instance in this environment, serving as both a runtime and an administrative port.
Protected Zone	Back-end controlled zone in which Sites hosting the protected APIs are located. All requests to these APIs must be designed to pass through PingAccess. PingFederate is accessible to API clients in this zone and is a standalone instance, serving as both a runtime and an administrative port.

### API Access Management production deployment architecture

This environment shows an API access management architecture.

There are many considerations when deploying a Production environment. For high availability and redundancy, the environment requires clustering and load-balancing. Load balancers are required as part of the networking infrastructure to achieve high availability by ensuring that requests are sent to available servers they are front-ending. Best practices in network design and security also include firewalls to ensure that only required ports and protocols are permitted across zones.

**Info:** PingAccess can provide high availability and basic load balancing for the protected web apps in the protected zone. See the Load Balancing Strategies documentation for more information.

The following environment example is a recommended production quality deployment architecture for an API access management use case.

The following table describes the three zones within this proposed architecture.

External Zone	External network where incoming API requests originate.
DMZ	Externally exposing segment where PingAccess is accessible to API clients. A minimum of two PingAccess engine nodes will be deployed in the DMZ to achieve high availability. Depending on your scalability requirements, more nodes may be required.
Protected Zone	Back-end controlled zone in which Sites hosting the protected APIs are located. All requests to these APIs must be designed to pass through PingAccess. PingFederate is accessible to API clients in this zone. A minimum of two PingFederate engine nodes will be deployed in the protected zone. Administrative nodes for both PingAccess and PingFederate may be co-located on a single machine to reduce hardware requirements

### Auditing and proxying proof of concept deployment architecture

This environment is used to emulate an auditing and proxying environment for testing purposes.

In the test environment, PingAccess can be set up with the minimum hardware requirements. Given these conditions, we do not recommend using this proposed architecture in a production deployment as it does not provide high availability.

The following table describes the three zones within this proposed architecture.

Zone	Description
External Zone	External network where incoming requests originate.
DMZ	Externally exposing segment where PingAccess is accessible to clients. PingFederate and PingAccess are standalone instances in this environment, serving as both runtime and administrative ports.
Protected Zone	Contains back-end Sites audited and proxied through PingAccess. Audit results are sent to an audit repository or digested by reporting tools. Many types of audit repository/tools are supported such as SIEM/GRC, Splunk, database, and flat files.

### Auditing and proxying production deployment architecture

This environment shows an auditing and proxying architecture.

There are many considerations when deploying a Production environment. For high availability and redundancy, the environment requires clustering and load-balancing. Load balancers are required as part of the networking infrastructure to achieve high availability by ensuring that requests are sent to available servers they are front-ending. Best practices in network design and security also include firewalls to ensure that only required ports and protocols are permitted across zones.

**Info:** PingAccess can provide high availability and basic load balancing for the protected web apps in the protected zone. See the Load Balancing Strategies documentation for more information.

The following environment example is a recommended production quality deployment architecture for an auditing/proxying use case.

The following table describes the three zones within this proposed architecture.

External Zone	External network where incoming requests originate.
DMZ	Externally exposing segment where PingAccess is accessible to clients. A minimum of two PingAccess engine nodes will be deployed in the DMZ. Depending on your scalability requirements, more nodes may be required.
Protected Zone	Contains back-end Sites audited and proxied through PingAccess. Audit results are sent to an audit repository or digested by reporting tools. Many types of audit repository tools are supported such as SIEM/GRC, Splunk, database, and flat files.

## Groovy Development Reference Guide

---

### Groovy

PingAccess provides the Groovy script and OAuth Groovy script rule types that enable the use of Groovy, a dynamic programming language for the Java Virtual Machine (see the [Groovy documentation](#)). Groovy scripts provide advanced rule logic that extends PingAccess rule development beyond the capabilities of the packaged rules.

Groovy scripts have access to important PingAccess runtime objects such as the [Exchange](#) and [PolicyContext](#) objects, which the scripts can interrogate and modify. Groovy script rules are invoked during the request processing phase of an exchange, allowing the script to modify the request before it is sent to the server. Groovy script rules are also invoked during the response, allowing the script to modify the response before it is returned to the client. The diagram below highlights the flow of Rule processing.

- During request processing, rules associated with the application are evaluated.
- The request passes through each of the rules before PingAccess allows it to proceed.
- The response passes through the rules in a manner based on your deployment:
  - In a proxy deployment, the response from the site passes through each of the rules.
  - In an agent deployment, the response to the agent indicating the policy approval or denial passes through each of the rules.

## Groovy Scripts

[Groovy](#) scripts provide advanced rule logic that extends PingAccess Rule development beyond the capabilities of the packaged rules.

Groovy scripts have access to important PingAccess runtime objects such as the [Exchange](#) and [PolicyContext](#) objects, which the scripts can interrogate and modify. Groovy script rules are invoked during the request processing phase of an exchange, allowing the script to modify the request before it is sent to the server. Groovy script rules are also invoked during the response, allowing the script to modify the response before it is returned to the client. See [Groovy](#) for more info about Groovy.

**Note:** Through Groovy scripts, PingAccess administrators can perform sensitive operations that could affect system behavior and security.

## Matchers

Groovy scripts must end execution with a Matcher instance. Matchers provide a framework for establishing declarative rule matching objects. You can use a Matcher from the list of [PingAccess Matchers](#) or from the [Hamcrest library](#).

The following are Hamcrest method examples for constructing access control policies with the Web Session Attribute rule using evaluations such as an OR group membership evaluation.

**allOf**

Matches if the examined object matches all of the specified Matchers. In this example, the user needs to be in both the sales and managers groups for this rule to pass.

```
allOf(containsWebSessionAttribute("group", "sales"),
      containsWebSessionAttribute("group", "managers"))
```

**anyOf**

Matches any of the specified Matchers. In this example, the rule passes if the user is in any of the specified groups.

```
anyOf(containsWebSessionAttribute("group", "sales"),
      containsWebSessionAttribute("group", "managers"),
      containsWebSessionAttribute("group", "execs"))
```

**not**

Inverts the logic of a Matcher to not match. In this example, the rule fails if the user is in both the sales and the managers groups.

```
not(allOf(containsWebSessionAttribute("group", "sales"),
          containsWebSessionAttribute("group", "managers")))
```

See [Matchers](#) for more information.

**Objects**

The following objects are available in Groovy. Click a link for more information on that object.

**[Exchange Object](#)**

Contains the HTTP request and the HTTP response for the transaction processed by PingAccess.

**[PolicyContext Object](#)**

Contains a map of objects needed to perform policy decisions. The contents of the map vary based on the context of the current user flow.

**[Request Object](#)**

Contains all information related to the HTTP request made to an application.

**[Response Object](#)**

Contains all information related to the site HTTP response.

**[Method Object](#)**

Contains the HTTP method name from the request made to an application.

**[Header Object](#)**

Contains the HTTP header information from the request made to an application or the HTTP header from a Site response.

**[Body Object](#)**

Contains the HTTP body from the application request or the HTTP body from the site response.

**[OAuthToken Object](#)**

Contains the OAuth access token and related identity attributes.

**[Logger Object](#)**

Configure and view the state of logging.

**[MediaType Object](#)**

Contains information related to the media type.

## Debugging/troubleshooting

Groovy script rules are evaluated when saved to ensure that they are syntactically valid. If a Groovy script rule fails to save, hover over the information icon to view additional information about the reason for the failure.

If a rule fails when it is run, information about the failure is added to the `<PA_HOME>/log/pingaccess.log` file.

**Info:** Some error messages about Groovy rule failures are only logged if DEBUG level output is enabled for the `com.pingidentity` logger.

## Body object

### Purpose

Accesses the Body object in Groovy `exc?.request?.body` or `exc?.response?.body`

The Body object contains the HTTP body from the application request or the HTTP body from the site response. The request HTTP body is sent on to the site after the rules are evaluated. The response HTTP body is sent on to the User-Agent after the response rules are evaluated.

### Groovy sample

```
//Checks the actual length of the body content and set the Content-Length
response header
def body = exc?.response?.body;
def header = exc?.response?.header;
header?.setContentLength(body?.getLength());
pass();
```

### Method summary

Method	Description
byte[] getContent()	Returns the body content of the request or response.
int getLength()	Returns the length of the body content.

## Exchange object

### Purpose

Accesses the Exchange object in Groovy - `exc`

The Exchange object is available to both the OAuth Groovy Script Rule and the regular Groovy Script Rule. PingAccess makes the Exchange object available to Groovy Script developers to provide request and response information for custom Groovy Rules.

The Exchange object contains both the HTTP request and the HTTP response for the transaction processed by PingAccess. You can use this object to manipulate the request prior to it being sent to the site. You can also use this object to manipulate the response from the site before it is sent to the client.

An instance of the Exchange object lasts for the lifetime of a single Application request. The Exchange object can be used to store additional information determined by the developer.

Some fields and methods for the Response Object are not available in scripts used with an Agent. See the Field Summary and Method Summary tables below for more information.

## Groovy sample

```
//Evaluate if the content length of the request is empty
if (exc?.request?.header?.contentLength > -1 )
{
    //Set a custom header in the request object
    exc?.request?.header?.add("X-PINGACCESS-SAMPLE", "SUCCESS")
    pass()
}
else
{
    println("Request content is empty") //Debugging statement
    fail()
}
```

## Method summary

Method	Description
Identity getIdentity()	Obtains the PingAccess representation of the identity associated with the request. This object will be null for requests to an unprotected application or an unauthenticated request to an anonymous resource.
Request getRequest()	Obtains the PingAccess representation of the request. This request is sent to the site with any changes that might be made in a Groovy script.
Response getResponse()	Obtains the PingAccess representation of the response. If the site has not been called, the response is null. This field is not available in scripts used with an Agent.
long getTimeReqSent()	Obtains the time, in milliseconds, when the request was sent to the site. This field is not available in scripts used with an Agent.
long getTimeResReceived()	Obtains the time, in milliseconds, when the response was received from the site. This field is not available in scripts used with an Agent.
String getRequestURI()	Returns the PingAccess URI that received the request.
String getRequestScheme()	Obtains the scheme used by the browser or other user agent that made the request.
Object getProperty(String key)	Returns the value of a custom property.
void setProperty(String key, Object value)	Sets a custom property.
SslData getSslData()	Obtains information established in the TLS handshake made with PingAccess.

## Headers object

### Purpose

Accesses the Headers object in Groovy `exc?.request?.header` or `exc?.response?.header`

The Headers object contains the HTTP Header information from the request made to an application or the HTTP Header from a site response. The [Request](#) HTTP Header is sent on to the site after the Rules are evaluated. The [Response](#) HTTP Header is returned to the client after the response Rules are evaluated.

Use the Headers object to add custom HTTP headers for site.

### Groovy sample

```
//Set a custom header for the Service request
def header = exc?.request?.header;
header?.add( "X-PINGACCESS-SAMPLE", "SUCCESS" );
pass();
```

### Method summary

Method	Description
void add(String key, String val)	Adds HTTP header fields for the request.  <b>Info:</b> Note that if Groovy Rules are used to inject HTTP headers for the backend protected application, the script must sanitize the same headers from the original client request.
String getAccept()	Returns the acceptable response Content-Types expected by the User-Agent.
void setAccept(String value)	Sets the acceptable response Content-Types expected by the User-Agent.
String getAuthorization()	Returns the authentication credentials for HTTP Authentication.
void setAuthorization(String username, String password)	Sets authentication credentials for HTTP Authentication.
String getConnection()	Returns the connection type preferred by the User-Agent.
void setConnection(List<String> values)	Sets the connection type preferred by the User-Agent.
int getContentLength()	Returns the request body content length.
void setContentLength(int length)	Sets the request body content length.
MediaType getContentType()	Returns media type of Header with Content type
void setContentType(String)	Sets the request body MIME type.
Map <String, String[]> getCookies()	Returns all cookies sent with the request.
void setCookie(String)	Overwrites the request's cookie header with the passed string. This method cannot be used to set cookies in the response header.
String getFirstCookieValue(String)	Returns the first cookie in the Cookie header.
String getFirstValue(String)	Returns the first value of the HTTP header specified by the name.
void setDate(Date date)	Sets the date of the message in the Date HTTP header.
List<GroovyHeaderFields> getAllHeaderFields()	Returns a list of GroovyHeaderFields.

Method	Description
String getHost()	Returns the hostname specified in the request.
void setHost(String value)	Sets the hostname for the request to the Site.
String getLocation()	Gets the redirect location URL for the response.
void setLocation(String value)	Sets the redirect location URL for the response.
String getProxyAuthorization()	Returns the proxy credentials.
void setProxyAuthorization(String value)	Sets the request proxy credentials.
void setServer(String value)	Sets the server name for the response.
List<String> getValues(String name)	Returns a list of string values for the supplied header name.
String getXForwardedFor()	Returns the originating IP address of the client and the proxies, if set.
void setXForwardedFor(String value)	Sets the IP Address for the client and the proxies.
boolean removeContentEncoding()	Removes the Content-Encoding header value. Returns true if the value has been removed.
boolean removeContentLength()	Removes the Content-Length header value. Returns true if the value has been removed.
boolean removeContentType()	Removes the Content-Type header value. Returns true if the value has been removed.
boolean removeExpect()	Removes the Expect header value. Returns true if the value has been removed.
boolean removeFields(String name)	Removes the header value specified by the name parameter. Returns true if the value has been removed.
boolean removeTransferEncoding()	Removes the Transfer-Encoding header value. Returns true if the value has been removed.

## Identity object

### Purpose

The Identity object contains information about the authenticated identity associated with the current HTTP request.

### Groovy sample

```
// Only allow access for an identity with subject "user"
def subject = exc?.identity?.subject

if ("user".equals(subject)) {
    pass()
} else {
    fail()
}
```

**Method summary**

Method	Description
String getSubject()	Returns the subject of the identity.
String getMappedSubject()	Returns the subject set by the identity mapping. If there is no identity mapping associated with the application, the return value will be null. If there is an identity mapping associated with the application, but the identity mapping did not determine a subject to map, the returned value may be the empty string.
String getTrackingId()	Returns the tracking identifier used in PingAccess logs. This value is not guaranteed to be globally unique and should be used for diagnostic purposes only
String getTokenId()	Returns the unique ID for the associated authentication token. This value may change when new tokens are issued for the same identity.
Date getTokenExpiration()	Returns a Date object representing the time at which the authentication token expires. This may be null if the authentication provider did not indicate an expiry.
JsonNode getAttributes()	Returns a JsonNode object representing the attributes of the identity.

**JsonNode object****Purpose**

The JsonNode object represents the attributes of an identity.

**Groovy sample**

```
// Only allow access if the user is in the group "staff"
def groups = exc?.identity?.attributes?.get("groups")

foundGroup = falseif (groups) {
    for (group in groups) {
        if ("staff".equals(group.asText())) {
            foundGroup = truebreak
        }
    }
}

if (foundGroup) {
    pass()
} else {
    fail()
}
```

**Method summary**

Method	Description
JsonNode get(String fieldName)	Gets the JsonNode representing a field of this JsonNode. This method will return null if no field exists with the specified name.
boolean has(String fieldName)	Returns true if this JsonNode has a field with the specified name.
java.util.Iterator<String> fieldNames()	Returns an java.util.Iterator providing access to the names of all the fields of this JsonNode.
boolean isTextual()	Returns true if this JsonNode represents a string value.
String asText()	Returns a string representation of this JsonNode. If this JsonNode is an array or object, this will return an empty string.
int intValue()	Returns an integer representation of this JsonNode. If this JsonNode does not represent a number, 0 is returned.
boolean isArray()	Returns true if this JsonNode is an array.
boolean isObject()	Returns true if this JsonNode is an object.
int size()	For an array JsonNode, returns the number of elements in the array. For an object JsonNode, returns the number of fields in the object. 0 otherwise.
java.util.Iterator<JsonNode> iterator()	Returns an java.util.Iterator over all JsonNode objects contained in this JsonNode. For an array JsonNode, the returned java.util.Iterator will iterate over all the elements in the array. For an object JsonNode, the returned java.util.Iterator will iterate over all field values in the object.

**Remarks**

A JsonNode implements java.lang.Iterable<JsonNode> so a for loop can be used to iterate over all the elements in an array JsonNode or the field values in an object JsonNode.

**Logger object****Purpose**

Accesses the Logger object.

**Method summary**

Method	Description
void trace(String format, Object... arguments)	Logs a TRACE level message based on the specified format and arguments.
void debug(String format, Object... arguments)	Logs a DEBUG level message based on the specified format and arguments.

Method	Description
void info(String format, Object... arguments)	Logs an INFO level message based on the specified format and arguments.
void warn(String format, Object... arguments)	Logs a WARN level message based on the specified format and arguments.
void error(String format, Object... arguments)	Logs an ERROR level message based on the specified format and arguments.
boolean isTraceEnabled()	Checks if the logger instance is enabled for the TRACE level.
boolean isDebugEnabled()	Checks if the logger instance is enabled for the DEBUG level.
boolean isInfoEnabled()	Checks if the logger instance is enabled for the INFO level.
boolean isWarnEnabled()	Checks if the logger instance is enabled for the WARN level.
boolean isErrorEnabled()	Checks if the logger instance is enabled for the ERROR level.

## MediaType object

### Purpose

Accesses the MediaType object.

### Method summary

Method	Description
Map getParameters()	Returns a list of parameters.
String getBaseType()	Returns the media base type.
String getSubType()	Returns the media sub type.
String getParameter(String)	Returns a string containing the value of the request parameter.
String getPrimaryType()	Returns the primary media type.

## Method object

### Purpose

Accesses the Method object in Groovy `exc?.request?.method`

The Method object contains the HTTP Method name from the request made to an application. The HTTP Method is sent on to the Site after the Rules are evaluated.

### Groovy sample

```
//Retrieve the HTTP Method name and make different decisions based on the
method name
def method = exc?.request?.method?.methodName
switch (method) {
    case "GET":
```

```

        println("GET")
        break;
    case "POST":
        println("POST")
        break;
    case "PUT":
        println("PUT")
        break;
    case "DELETE":
        println("DELETE")
        break;
    default:
        println("DEFAULT")
        pass()
}

```

### Method summary

Method	Description
String getMethodName()	Returns the name of the HTTP Method ( GET, PUT, POST, DELETE, HEAD).

## OAuth Token object

### Purpose

Accesses the OAuth Token object in Groovy `policyCtx?.context.get("oauth_token")`

The OAuthToken object contains the OAuth access token and related identity attributes. The OAuthToken instance is available only for OAuth Groovy Script Rules.

### Groovy sample

```

def scopes = policyCtx?.context.get("oauth_token)?.scopes
def attr = policyCtx?.context.get("oauth_token)?.attributes
def username =
    policyCtx?.context.get("oauth_token)?.attributes?.get("username)?.get(0)
exc?.request?.header?.add("x-scopes", "$scopes")
exc?.request?.header?.add("x-attributes", "$attr")
exc?.request?.header?.add("x-username", "$username")
pass()

```

### Method summary

Method	Description
Instant getExpiresAt()	Contains the expiration instant of the OAuth access token.
Instant getRetrievedAt()	Contains the instant that the OAuth access token was retrieved from PingFederate.
String getTokenType()	Contains the type of OAuth access token. (Bearer, JWT).
String getClientId()	Contains the client ID associated with the OAuth access token.

Method	Description
Set getScopes()	Contains the set of scopes associated with the OAuth access token.
Map<String, List<String>> getAttributes()	Contains a map of identity attributes specific to the user.

## PolicyContext object

### Purpose

Accesses the Policy Context object in Groovy `policyCtx`

The PolicyContext object is a map of objects needed to perform policy decisions. The contents of the map vary based on the context of the current user flow. A common example is OAuth token information stored in an OAuthToken object contained within the context map. In this example, an OAuthToken object is retrieved from the policy context by using the `oauth_token` key. The OAuthToken object is available only for the OAuth Groovy Script Rule.

### Groovy sample

```
def oauthToken = policyCtx?.context.get("oauth_token")
```

### Method summary

Method	Description
Map<String, Object> getContext()	Container for the <a href="#">OAuthToken object</a> .
Exchange getExchange()	Returns the exchange a message relates to.

## Request object

### Purpose

Accesses the Request object in Groovy `exc?.request`

The Request object contains all information related to the HTTP request made to an application. The request instance is sent on to the site after the Rules are evaluated.

Some fields and methods for the Response Object are not available in scripts used with an Agent. See the Field Summary and Method Summary tables below for more information.

### Groovy sample

```
//Retrieve the request object from the exchange object
def request = exc?.request
def contentType = request?.headers?.getContentType()
def containsJson = contentType?.matchesBaseType("application/json")
//Check to make sure the request body contains JSON
if (!containsJson) {
  fail()
} else {
  pass()
}
```

**Field summary**

Field	Description
String uri	Returns the PingAccess URI that received the request.
void setUri(String)	Sets the PingAccess URI.

**Method summary**

Method	Description
<i>Method</i> getMethod	Contains the HTTP method information from the request sent to the application.
<i>Header</i> getHeader	Contains the HTTP header information from the request sent to the application.   <b>Warning: Warning:</b> Previously executed custom Rules can modify these values.
<i>Body</i> getBody	Contains the HTTP body information from the request sent to the application. This field is not available in scripts used with an Agent.   <b>Warning: Warning:</b> Previously executed custom Rules can modify these values.
Map<String, String[]> getQueryStringParams()	Parses and returns the query string parameters from the request. If the query string parameters cannot be parsed due to formatting errors, this method will throw a URISyntaxException. Groovy scripts that use this method are not required to catch this exception. Scripts that choose not to catch this exception will fail if the query string parameters are invalid.
Map<String, String[]> getPostParams()	Parse the form parameters from the body content of the request, assuming the content is encoded using the encoding defined by the application/x-www-form-urlencoded content type.
void setBodyContent(byte[] content)	Replaces the body content of the request. This method will also adjust the Content-Length header field to align with the length of the specified content.

**Response object****Purpose**

Accesses the Response object in Groovy `exc?.response`

The Response object contains all information related to the Service HTTP response. The response instance is sent on to the User-Agent after the Rules are evaluated.

The fields and methods for the Response Object are not available in scripts used with an Agent.

## Groovy sample

```

if(exc?.response && exc?.identity) {
    exc.response.header.add("PA-Tracking-ID", exc.identity.trackingId)
}
pass()

```

## Field summary

Field	Description
int getStatusCode()	Contains the HTTP response status code.
void setStatusCode(int)	Sets the status code from an integer.
String getStatusMessage()	Contains the HTTP response status message.
void setStatusMessage(String)	Sets the status message from a string.

## Method summary

Method	Description
boolean isRedirect()	Returns true if the status code is in the 300's.
<a href="#">Header</a> getHeader	Contains the HTTP header information from the response.   <b>Warning:</b> Previously executed custom Rules can modify these values.
<a href="#">Body</a> getBody	Contains the HTTP body information from the response.   <b>Warning:</b> Previously executed custom Rules can modify these values.
void setBodyContent(byte[] content)	Replaces the body content of the response. This method will also adjust the Content-Length header field to align with the length of the specified content.

## SslData object

### Purpose

The SslData object provides access to information established in the TLS handshake with PingAccess.

### Groovy sample

```

// Force TLS client authentication
def certChain = exc?.sslData?.clientCertificateChain
if(certChain && !certChain.isEmpty())
{
    pass();
}
else
{
    fail();
}

```

**Method summary**

Method	Description
List<String> getSniServerNames()	Returns a list of SNI server_names sent by the user agent in the TLS handshake. Empty if the user agent did not utilize the SNI TLS extension.
List<java.security.cert.X509Certificate> getClientCertificateChain()	Returns the certificate chain presented by the user agent in the TLS handshake. Empty if the user agent did not utilize TLS client authentication.

**Groovy script examples****OAuth Policy context example**

In some instances, it may be necessary to transmit identity information to Sites to provide details of the user attempting to access a Site. In such instances, Groovy scripts can be used to inject identity information into various portions of the HTTP request to the target. In this example, the Site is expecting the identity of the user to be conveyed via the `User` HTTP header. This can be accomplished using the OAuth Groovy Script Rule and the following Groovy script:

```
user=policyCtx?.context.get("oauth_token")?.attributes?.get("user")?.get(0)
exc?.request?.header?.add("User", "$user")
pass()
```

More complex Groovy script logic:

```
test = exc?.request?.header?.getFirstValue("test");
if(test != null && test.equals("foo"))
{
    //rule will fail evaluation if Test header has value 'foo'
    fail()
}
else
{
    //rule will pass evaluation is Test header has value of anything else
    //or isn't present
    pass()
}
```

Set an exchange property named `com.pingidentity.policy.error.info` so the value will be available for the `$info` variable in error templates when an error is encountered. The `$info` variable can be set by a Groovy Script rule or an OAuth Groovy Script rule.

```
exc?.setProperty("com.pingidentity.policy.error.info", "this value will be
passed to the template in $info variable")
not(anything())
```

Create a white listing rule for certain characters.

```
if (!exc?.request?.uri?.matches("[\\p{Po}\\p{N}\\p{Z}\\p{L}\\p{M}\\p{Zs}\\./
_\\-\\(\\)\\{\\}\\[\\]]*"))
{
    fail()
}
else
{
    pass()
}
```

Add a cookie to the response.

```
// Construct the cookie value
value = "cookie-value"
cookieHeaderFieldValue = "ResponseTestCookie=${value}; Path=/"

// Add the cookie on to the response
exc?.response?.header?.add("Set-Cookie", cookieHeaderFieldValue)

pass()
```

Comb an AND and OR, invoking an existing rule Matcher.

```
if ((anyOf(containsWebSessionAttribute("engineering",
    "true"), containsWebSessionAttribute("marketing", "true")) &&
    (containsWebSessionAttribute("manager", "true")))
    {pass()}
}
else{
fail()
}
```

## Matchers

Groovy script rules and OAuth Groovy script rules must end execution with a Matcher instance. This could either be a Matcher from the list of PingAccess Matchers or from the [Hamcrest library](#) (for more information on Hamcrest, see the [Hamcrest Tutorial](#)).

### Examples

#### Example 1 - Simple Groovy rule inserts a custom HTTP header

```
test = "let's get Groovy!"
exc?.response?.header?.add("X-Groovy", "$test")
pass()
```

In the sample rule above, the script ends with a call to the Matcher `pass()`. The `pass()` Matcher signals that the rule has passed.

#### Example 2 - OAuth Groovy rule checks the HTTP method and confirms the OAuth scope

```
//Get the HTTP method name
def methodName = exc?.request?.method?.methodName()
if (methodName == "POST") {
    hasScope("WRITE")
} else {
    fail()
}
```

In the sample rule above, a Matcher is evaluated at the end of each line of execution. The first Matcher used is the `hasScope()` Matcher that confirms if the OAuth access token has the `WRITE` scope. If this is true, the rule passes.

The `fail()` Matcher combination is evaluated when the `methodName` does not equal `POST`. This Matcher combination evaluates to false.

### Ping Access Matchers

The following table lists the Matchers available for the Groovy script rule and the OAuth Groovy script rule.

Matcher	Description
pass()	Signals that the rule has passed.
fail()	Signals that the rule has failed.
inIpRange(String cidr)	<p>Validates the source IP address of the request against the cidrstring parameter in CIDR notation. When Source IP headers defined in the <a href="#">HTTP Requests</a> page are found, the source IP address determined from those headers is used as the source address.</p> <p>For agents, this value is also potentially controlled by the override options on the Agent settings.</p> <p><b>Example:</b> <code>inIpRange("127.0.0.1/8")</code></p>
inIpRange(java.net.InetAddress ipAddress, int prefixSize)	<p>Validates the source IP address against the ipAddress and the prefixSize parameters specified individually. When source IP headers defined in the <a href="#">HTTP Requests</a> page are found, the source IP address determined from those headers is used as the source address.</p> <p>For agents, this value is also potentially controlled by the override options on the Agent settings.</p> <p><b>Example:</b>  <code>inIpRange(InetAddress.getByName("127.0.0.1"), 8)</code> is equivalent to <code>inIpRange("127.0.0.1/8")</code></p>
inIpRange(String cidr, String listValueLocation, boolean fallBackToLastHopIp, String... headerNames)	<p>Validates the source IP address in the first of the specified headerNames using the cidr value. Can be specified as part of a Groovy script as a means of overriding the configuration stored in PingAccess for a specific Groovy script rule.</p> <p>Valid values for the listValueLocation parameter are FIRST, LAST, and ANY. This parameter controls where, in a multivalued list of source IP addresses, the last source should be taken from. If ANY is used, if any of the source IP addresses in a matching header match the CIDR value, the Matcher evaluates to true.</p> <p><b>Example:</b> <code>inIpRange("127.0.0.1/8", "LAST", true, "X-Forwarded-For", "Custom-Source-IP")</code></p>
inIpRange(java.net.InetAddress address, int prefixSize, String listValueLocation, boolean fallBackToLastHopIp, String... headerName)	<p>Validates the source IP address in the first of the specified headerNames using the address and prefixSize values. In all other respects, this Matcher behaves the same as the version that uses a cidr value for comparison.</p> <p><b>Example:</b>  <code>inIpRange(InetAddress.getByName("127.0.0.1"), 8, "LAST", true, "X-Forwarded-For", "Custom-Source-IP")</code></p>

Matcher	Description
<pre>requestXPathMatches(String   xpathString, String xpathValue)</pre>	<p>Validates that the value returned by the <code>xPathString</code> parameter is equal to the <code>xPathValue</code> parameter.</p> <p><b>Example:</b> <code>requestXPathMatches("//header[@name='Host']/text()", "localhost:3000")</code></p>
<pre>inTimeRange(String startTime, String   endTime)</pre>	<p>Validates that the current server time is between the <code>startTime</code> and <code>endTime</code> parameters.</p> <p><b>Example:</b> <code>inTimeRange("9:00 am", "5:00 pm")</code></p>
<pre>inTimeRange24(String startTime, String   endTime)</pre>	<p>Validates that the current server time is between the specified 24-hour formatted time range between the <code>startTime</code> and <code>endTime</code> parameters.</p> <p><b>Example:</b> <code>inTimeRange24("09:00", "17:00")</code></p>
<pre>requestHeaderContains(String field,   String value)</pre>	<p>Validates that the HTTP header field value is equal to the value parameter.</p> <p><b>Example:</b> <code>requestHeaderContains("User-Agent", "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_8_3) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/27.0.1453.93 Safari/537.36")</code></p>
<pre>requestHeaderContains(Map&lt;String,   String&gt; fieldValuesMap, boolean   caseSensitive)</pre>	<p>Validates that all of the HTTP header fields map to the associated value. The first <code>fieldValuesMap</code> string contains the HTTP header name, and the second string contains the value to compare the incoming request header value with.</p> <p>The <code>caseSensitive</code> parameter determines whether a case-sensitive comparison is performed on the value.</p> <p>The second string in the <code>fieldValuesMap</code> supports Java regular expressions.</p> <p>If multiple pairs of strings are present in the <code>fieldValuesMap</code> parameter, then all conditions must be met in order for the Matcher to pass.</p> <p><b>Example:</b> <code>requestHeaderContains(['User-Agent': 'Mozilla/5.0', 'Cookie': 'JSESSIONID'], false)</code></p>

Matcher	Description
<pre>requestPostFormContains(Map&lt;String, String&gt; fieldValuesMap, boolean caseSensitive)</pre>	<p>Validates that all of the HTTP form fields maps to the associated value. The first fieldValuesMap string contains the form header name, and the second string contains the value to compare the incoming request header value with.</p> <p>The caseSensitive parameter determines whether a case-sensitive comparison is performed on the value.</p> <p><b>Note:</b> This Matcher determines whether to use fields passed in the URL or forms with a content-type header of application/x-www-form-urlencoded.</p> <p>The second string in the fieldValuesMap supports Java regular expressions.</p> <p>If multiple pairs of strings are present in the fieldValuesMap parameter, then all conditions must be met in order for the Matcher to pass.</p> <p><b>Example:</b></p> <pre>requestPostFormContains(['email': '@example.com', 'phonenumber': '720'], false)</pre>
<pre>requestHeaderDoesntContain(String field, String value)</pre>	<p>Validates that the HTTP header field value is not equal to the value parameter.</p> <p><b>Example:</b></p> <pre>requestHeaderDoesntContain("User-Agent", "InternetExplorer")</pre>
<pre>requestBodyContains(String value)</pre>	<p>Validates that the HTTP body contains the value parameter.</p> <p><b>Example:</b></p> <pre>requestBodyContains("production")</pre>
<pre>requestBodyDoesntContain(String value)</pre>	<p>Validates that the HTTP body does not contain the value parameter.</p> <p><b>Example:</b></p> <pre>requestBodyDoesntContain("test")</pre>
<pre>containsWebSessionAttribute(String attributeName, String attributeValue)</pre>	<p>Validates that the PA token contains the attribute name and value.</p> <p><b>Example:</b></p> <pre>containsWebSessionAttribute("sub", "sarah")</pre>
<pre>containsACRValues(String value)</pre>	<p>Validates that the PA token contains a matching ACR value.</p>

The following table lists the Matchers available to only the OAuth Groovy rule.

Matcher	Description
<code>hasScope(String scope)</code>	Validates that the OAuth access token contains the scope parameter.  <b>Example:</b> <code>hasScope("access")</code>
<code>hasScopes(String... scopes)</code>	Validates that the OAuth access token contains the list of scopes.  <b>Example:</b> <code>hasScopes("access", "portfolio")</code>
<code>hasAttribute(String attributeName, String attributeValue)</code>	Checks for an attribute value within the current OAuth2 policy context.  <b>Example:</b> <code>hasAttribute("account", "joe")</code>

## Performance Tuning Reference Guide

---

### Performance tuning

While PingAccess has been engineered as a high performance engine, its default configuration may not match your deployment goals nor the hardware you have available.

Consult the following sections to optimize various aspects of a PingAccess deployment for maximum performance.

**Info:** An additional document related to performance, the PingAccess Capacity Planning Guide, is also available to customers as a performance data reference. This document is available from the [Customer Portal](https://ping.force.com/Support) ([ping.force.com/Support](https://ping.force.com/Support)).

### Java tuning

One of the most important tuning options you can apply to the Java Virtual Machine (JVM) is to configure how much heap (memory for runtime objects) to use.

The JVM grows the heap from a specified minimum to a specified maximum. If you have sufficient memory, best practice is to “fix” the size of the heap by setting minimum and maximum to the same value. This allows the JVM to reserve its entire heap at startup, optimizing organization and eliminating potentially expensive resizing.

By default, PingAccess fixes the Java heap at 512 megabytes (MB). This is a fairly small footprint and not optimal for supporting higher concurrent user loads over extended periods of activity. If you expect your deployment of PingAccess to serve more than 50 concurrent users (per PingAccess node if deploying a cluster), we recommend that you increase the heap size.

#### Configure JVM crash log in Java startup

You can enable or disable the JV crash log, or change the location where it is stored.

#### About this task

The JVM crash log location is specified in `run.bat` (Windows) or `run.sh` (Linux) and is enabled by default.

#### Steps

1. Open `<PA_HOME>/bin/run.bat` (Windows) or `<PA_HOME>/bin/run.sh` (Linux) for editing.
2. To disable JVM crash log reporting, comment out the line that specifies the JVM crash log location. For example, `#ERROR_FILE="-XX:ErrorFile=$PA_HOME/log/java_error%p.log"`.

- To enable JVM crash log reporting, remove the comment tag and make the line active. For example,
 

```
ERROR_FILE="-XX:ErrorFile=$PA_HOME/log/java_error%p.log".
```

### Configure memory dumps in Java startup

You can enable or disable JVM memory dump, or change the location where the dump is stored.

#### About this task

The JVM memory dump location is specified in `run.bat` (Windows) or `run.sh` (Linux) and is disabled by default.

#### Steps

- Open `<PA_HOME>/bin/run.bat` (Windows) or `<PA_HOME>/bin/run.sh` (Linux) for editing.
- To enable JVM memory dump, remove the comment tag on the line that specifies the JVM memory dump location. For example, `HEAP_DUMP="-XX:+HeapDumpOnOutOfMemoryError -XX:HeapDumpPath=$PA_HOME/log"`.
- To disable JVM memory dump, comment out the line. For example, `#HEAP_DUMP="-XX:+HeapDumpOnOutOfMemoryError -XX:HeapDumpPath=$PA_HOME/log"`.

### Modify the Java heap size

You can modify the Java heap size for both Windows and Linux installations, including their services

#### Steps

- Open the `jvm-memory.options` file located in `PA_HOME/conf`.
- Specify overall heap size by modifying the `#Minimum heap size` and `#Maximum heap size` parameters.
  - Modify `-Xms512m` to change the `#Minimum heap size value`
  - Modify `-Xmx512m` to change the `#Maximum heap size value`

Specify units as `m` (megabytes) or `g` (gigabytes).
- Specify young generation size by modifying the `#Minimum size for the Young Gen space` and `#Maximum size for the Young Gen space variables`.
  - Modify `-XX:NewSize=256m` to change the `#Minimum size for the Young Gen space value`
  - Modify `-XX:MaxNewSize=256m` to change the `#Maximum size for the Young Gen space value`

Set values to 50% of `#Minimum heap size` and `#Maximum heap size`.

**Info:** Not advisable if selecting the G1 collector (see [Garbage Collector Configuration](#) for more information).

- If you are running PingAccess as a Windows service, run the `generate-wrapper-jvm-options.bat` file located in `PA_HOME/sbin/windows`.
 

This file applies the changes from the `jvm-memory.options` file to the `wrapper-jvm-options.conf` file, which is used by the Windows service.

## Operating system tuning

This section contains tuning recommendations for your operating system.

The tuning recommendations provided here are particularly useful in preventing deployment issues in high capacity environments. See the included topics for guidance specific to your operating system.

### Linux tuning

This section describes tuning recommendations for the Linux operating system environment.

Implement these recommendations to prevent deployment issues, particularly in high capacity environments. The following settings will increase the performance and capacity of the networking (particularly TCP) stack and file descriptor usage, respectively, enabling PingAccess to handle a high volume of concurrent requests.

### Network/TCP tuning:

Add/Modify the following entries in /etc/sysctl.conf

```
##TCP Tuning##
# Controls the use of TCP syncookies (default is 1)
# and increase the number of outstanding syn requests allowed.
net.ipv4.tcp_syncookies=1
net.ipv4.tcp_max_syn_backlog=8192

# Increase number of incoming connections.
# somaxconn defines the number of request_sock structures allocated
# per each listen call.
# The queue is persistent through the life of the listen socket.
net.core.somaxconn=4096

# Increase number of incoming connections backlog queue.
# Sets the maximum number of packets, queued on the INPUT side,
# when the interface receives packets faster
# than kernel can process them.
net.core.netdev_max_backlog=65536

# increase system IP port limits
net.ipv4.ip_local_port_range=2048 65535

# Turn on window scaling which can enlarge the transfer window:
net.ipv4.tcp_window_scaling=1

# decrease TCP timeout
net.ipv4.tcp_fin_timeout=10

# Enables fast recycling of TIME_WAIT sockets.
# (While this may increase performance, it can introduce issues with
# persistent keep-alive connections when interacting with upstream/
# downstream network appliances (load balancers, proxies, etc.).
# This setting should only be enabled after the system administrator
# reviews security considerations.)
net.ipv4.tcp_tw_recycle=0

# Allow reuse of sockets in TIME_WAIT state for new connections
# (While this may increase performance, use with caution according
# to the kernel documentation. This setting should only be enabled
# after the system administrator reviews security considerations.)
net.ipv4.tcp_tw_reuse=0

# Increase the read and write buffer space allocatable
# (minimum size, initial size, and maximum size in bytes)
net.ipv4.tcp_rmem = 4096 65536 16777216
net.ipv4.tcp_wmem = 4096 65536 16777216

# The maximum number of packets which may be queued
# for each unresolved address by other network layers
net.ipv4.neigh.default.unres_qlen=100
net.ipv4.neigh.eth0.unres_qlen=100
net.ipv4.neigh.em1.unres_qlen=100

# Default Socket Receive and Write Buffer
net.core.rmem_default=8388608
```

```
net.core.wmem_default=8388608
#####
```

### Increase File Descriptor limits:

Add/Modify the following lines in `/etc/security/limits.conf`:

```
pingAccessAccount soft nofile 10400
pingAccessAccount hard nofile 10400
```

where `pingAccessAccount` is the user account used to run the `PingAccess` java process (or `*` for all users).

### Windows tuning

This section describes tuning recommendations for the Windows (version 7 and up) operating system environment.

Implement these recommendations to prevent deployment issues, particularly in high capacity environments. The following settings will increase the performance and capacity of network (specifically the TCP socket) connectivity, enabling `PingAccess` to handle a high volume of concurrent requests.

#### Increase the number of available ephemeral ports

1. View ephemeral ports: `netsh int ipv4 show dynamicportrange tcp`
2. Increase ephemeral ports: `netsh int ipv4 set dynamicport tcp start=1025 num=64510`
3. Reboot the machine.
4. View and confirm updated port range: `netsh int ipv4 show dynamicportrange tcp`

#### Reduce socket TIME\_WAIT delay

1. Click **Start > Run**, type `regedit` and click **OK** to open the Registry Editor.
2. Navigate to `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Tcpip\Parameters`.
3. Create a new DWORD value (32 bit) and provide the name `TcpTimedWaitDelay`.
4. Set a decimal value of 30.
5. Reboot the machine.

## Garbage collector configuration

This table provides guidance for configuring the garbage collector.

Selecting the appropriate garbage collector depends on the size of the heap and available CPU resources. The following is a table of available collectors and some general guidance on when and how to use them.

Specify the garbage collector using the `jvm-memory.options` file located in `PA_HOME/conf`. Modify the parameter beneath `#Use the parallel garbage collector` using the information provided below.

Garbage Collector	Description	Modifications
Parallel	<ul style="list-style-type: none"> <li>• Best used with heaps 4GB or less</li> <li>• Full stop-the-world copying and compacting collector</li> <li>• Uses all available CPUs (by default) for garbage collection</li> </ul>	Default collector for server JVM. No modification is required.

Garbage Collector	Description	Modifications
Concurrent Mark Sweep (CMS)	<ul style="list-style-type: none"> <li>• Best for heaps larger than 4GB with at least 8 CPU cores</li> <li>• Mostly a concurrent collector</li> <li>• Some stop-the-world phases</li> <li>• Non-Compacting</li> <li>• Can experience expensive, single threaded, full collections due to heap fragmentation</li> </ul>	Set to #XX: +UseConcMarkSweepGC in <code>jvm-memory.options</code> .
Garbage First (G1)	<ul style="list-style-type: none"> <li>• Best for heaps larger than 6GB with at least 8 CPU cores</li> <li>• Combination concurrent and parallel collector with small stop-the-world phases</li> <li>• Long-term replacement for CMS collector (does not suffer heap fragmentation like CMS)</li> </ul>	Set to #XX: +UseG1GC in <code>jvm-memory.options</code> . Also disable #Minimum size for the Young Gen space and #Maximum size for the Young Gen space tuning. Explicit sizing adversely affects pause time goal. To disable, comment the lines out in the script.

## Acceptor threads

You can configure the pool of acceptor threads based on your environment.

PingAccess uses a pool of threads to respond to HTTP/S requests made to the TCP port(s) in use. This applies to both administrative and runtime engine listening ports. Acceptor threads read user requests from the administrative or runtime port and pass the requests to worker threads for processing. For performance, only one acceptor thread need be used in most situations. On larger multiple CPU core machines, more acceptors may be used.

To modify, open the `run.properties` file located in the `conf` directory of your PingAccess deployment and specify the number of acceptors you want to use on the following lines:

```
admin.acceptors=N
```

```
engine.http.acceptors=N
```

```
agent.http.acceptors=N
```

Where *N* represents the number of acceptor threads.

## Worker threads

You can modify the minimum and maximum number of worker threads to increase performance.

PingAccess uses a pool of *worker* threads to process user requests and a separate pool to process agent requests. Worker threads receive user requests from Acceptor threads, process them, respond back to the client and then return to the pool for reuse. By default, PingAccess starts with a minimum of five worker threads and grows as needed (unbounded by default). You can define the minimum and maximum number of Worker threads in each pool by adding and/or modifying properties found in the `run.properties` file.

To set values, open the `run.properties` file located in the `conf` directory of your PingAccess deployment. If the properties do not exist in the file add them.

```
engine.httptransport.coreThreadPoolSize=N
engine.httptransport.maxThreadPoolSize=N
```

and

```
agent.httptransport.coreThreadPoolSize=N
agent.httptransport.maxThreadPoolSize=N
```

Where *N* represents the number of worker threads.

Maintenance of the pool is such that if the number of threads in the pool exceeds the value of `engine.httptransport.coreThreadPoolSize`, threads idle for 60 seconds are terminated and removed from the pool. The idle timeout value is not modifiable. However, if the values of `engine.httptransport.coreThreadPoolSize` and `engine.httptransport.maxThreadPoolSize` are the same, a fixed sized pool is created and idle threads are not terminated and removed. Similarly for `agent.httptransport.coreThreadPoolSize` and `agent.httptransport.maxThreadPoolSize`.

Since the pool by default is allowed to grow and shrink based on demand, it is recommended that you tune the `engine.httptransport.coreThreadPoolSize` and `agent.httptransport.coreThreadPoolSize` (minimum) to satisfy moderate demand on the system. We recommend a minimum of 10 threads per available CPU core as a good value to support up to twice the number of concurrent users without error or significant degradation in performance.

## Backend server connections

PingAccess provides the Max Connections option to control and optimize connections to the proxied site.

### Max Connections

Connections to PingAccess are not explicitly connections to the proxied site. PingAccess creates a pool of connections, unlimited in size by default, that are multiplexed to fulfill client requests. Maintenance of the pool includes creating connections to the site when needed (if none are available) and removing connections when they are closed by the backend server due to inactivity.

In certain situations it can be advantageous to limit the number of connections in the pool for a given Web site. If, for example, the Web site is limited to the number of concurrent connections it can handle or has specific HTTP Keep Alive settings, limiting the number of connections from PingAccess can improve overall performance by not overloading the backend server. In the event that all connections in the pool are in use, a requesting thread waits for one to become available. Assuming that response time from the backend site is sufficiently fast, the time spent waiting for a connection is likely to be less than if the system becomes overloaded.

**Info:** We strongly recommended that you understand the limits and tuning of the server application being proxied. Setting the **Max Connections** value too low may create a bottleneck to the proxied site, setting the value too high (or unlimited) may cause PingAccess to overload the server.

See Sites documentation for information on setting **Max Connections**.

## Logging and Auditing

PingAccess uses a high performance, asynchronous logging framework to provide logging and auditing services with as low impact to overall application performance as possible.

### Logging

You can modify your logging settings to increase performance.

Although logging is handled by a high performance, asynchronous logging framework, it is more efficient to the system overall to log the minimum amount of information required. We highly recommend that you review the section of the documentation for logging and adjust the level to the lowest, most appropriate level to suit your needs.

## Auditing

You can modify your environment's auditing settings based on your security and performance needs.

As with logging, auditing is provided by the same high performance, asynchronous logging framework. Furthermore, auditing messages can be written to a database instead of flat files, decreasing file I/O. If you do not require auditing for interactions with a Resource or between PingAccess and PingFederate, it is more efficient to disable audit logging. However, if you do require auditing services and have access to a Relational Database Management System (RDBMS), we recommend auditing to a database. You will see a decrease in disk I/O, which may result in increased performance depending on database resources.

## Agent tuning

You can modify the properties of your PingAccess agents to improve performance.

Several properties in the `agent.properties` file can be configured for increased performance. See the agent documentation for [Apache](#) or [IIS](#) for more information on agent configuration and setting properties.

### Max Connections

Connections from the agent to PingAccess are limited by `agent.engine.configuration.maxConnections`. Though the default is set to 10, the PingAccess policy server sees optimal performance at 50 concurrent requests per CPU. In certain situations it can be advantageous to increase the number of connections. In the event that all connections in the pool are in use, a requesting thread waits for one to become available. Assuming that response time to PingAccess is sufficiently fast, the time spent waiting for a connection is likely to be less than if the system becomes overloaded. Note that this is the maximum number of connections per worker process, and not simply the total number of workers the agent has access to. Setting the `agent.engine.configuration.maxConnections` value too low may create a bottleneck to PingAccess, and setting the value too high may cause PingAccess to become overloaded.

### Max Tokens

By default, the maximum number of cached tokens in an agent is unlimited. In certain situations it can be advantageous to limit the size of the cache for the agent, as a smaller cache has a smaller memory footprint, freeing up memory available to the application for servicing requests. However, when the token cache limit is reached, the least recently used token-policy mapping will be removed from the cache. If that token-policy mapping happens to be needed again, the agent will have a cache miss, resulting in the need to obtain a new token-policy mapping from PingAccess.

## PingAccess User Interface Reference Guide

---

### PingAccess User Interface Reference Guide

This guide provides a reference for configuration of PingAccess features and components. Use this guide in conjunction with PingAccess use case documentation for a comprehensive set of instructions so you can get the most from your PingAccess implementation.

For ease of use, navigation of this guide is modeled after the PingAccess user interface. To learn more about configuration options for a particular screen, navigate to its topic in the same manner that you navigate the PingAccess user interface.

To learn about PingAccess, including its features and functions, see the [PingAccess Overview](#).

## Applications

The **Applications** tab contains controls for managing applications, resources, and redirects.

Choose from one of the following sections:

- [Applications](#) on page 172

- [Global unprotected resources](#) on page 178
- [Redirects](#) on page 179

## Applications

Applications represent the protected web applications and APIs to which client requests are sent.

Applications are composed of one or more resources, have a common Virtual Host and Context Root, and correspond to a single target site. Applications may also use a common Web Session and Identity Mapping. Access control and request processing rules can be applied to applications and their resources on the Policy Manager page to protect them. Applications can be protected by PingAccess Gateway or PingAccess Agent. In a gateway deployment, the target application is specified as a Site. In an agent deployment, the application destination is an Agent.

There are 3 application types:

- Web
- API
- Web + API

Web + API applications allow administrators to configure both Web and API settings for an application. These applications are able to switch between web and API processing behaviors on the fly based on whether the inbound request contains a web session cookie (web) or an OAuth token (API). If the inbound request contains neither, PingAccess will fallback to the method you specify as the Fallback Type for the application.

Use this page to define the applications which PingAccess protects and to which client requests are ultimately forwarded. You can use resources to partition the application into areas requiring distinct access control. Each Application contains at least a Root Resource. The combination of Virtual Server and Context Root must be unique for each Application.

## About SPA support

SPA Support merges the conventional 401 unauthorized response of an API application with the traditional 302 redirect response of a web application when a client request does not contain an authentication token. The SPA Supported result is a 401 response containing a JavaScript body that can initiate a 302 redirect. API clients will ignore the JavaScript body and react appropriately to the 401 response. However, browser clients will disregard the 401 response and execute the JavaScript body resulting in a redirect to the token provider to authenticate. Since clients self-select the portion of the response they are prepared to process, the result is a seamless authentication experience regardless of the client type.

SPA support can be used for all application types. When SPA support is enabled for Web + API applications, where a variety of client types are expected to communicate with the application, a fallback type is no longer required since both web and API clients will be properly redirected to authenticate by the same response. It may also benefit Web or API application types, for example, if a new version of a web application contains JavaScript framework components to call APIs. In this case, SPA Support may help mitigate issues in responding to different client types for authentication but it will not enable the full features of the other application type. You would need to migrate the application to a Web + API configuration in order to take advantage of the full functionality, such as that for authentication, rules, or identity mapping.

## Adding an application

You can add a new application.

### Steps

1. Navigate to **Applications > Applications**.
2. Click **+ Add Application**.
3. Complete the fields on the screen using [Manage Applications - Field Descriptions](#) as a guide.
4. Click either **Save** or **Save & Go to Resources** when finished. The latter option allows you to configure additional application resources.

**Note:** When you save the application, PingAccess verifies the Redirect URI for the Application's virtual host is configured in the PingFederate. If PingAccess determines that the Redirect URI is not defined, you will receive the following warning:

```
Save succeeded. Unable to find a matching Redirect URI in the PingFederate
OAuth Client configuration for [<VHost>/pa/oidc/cb]
```

If you see this warning, ensure that there is a Redirect URI that matches configured. If you have a wildcard in your Virtual Host configuration, ensure the Redirect URI list includes the same wildcard host definition, otherwise you may have a configuration that is only valid in some circumstances.

This validation is performed if the **Application Type** is Web or Web + API, a **Web Session** is selected, and the PingFederate Administration connection is configured.

### Application Field Descriptions

This table describes the fields available for managing applications at **Applications > Applications**.

Field	Required	Description
Name	Yes	A unique name for the application.
Description	No	An optional description for the application.
Context Root	Yes	The context at which the application is accessed at the site. <b>Note:</b> This value must meet the following criteria: <ul style="list-style-type: none"> <li>• It must start with /.</li> <li>• It can contain additional / path separators.</li> <li>• It must not end with /.</li> <li>• It must not contain wildcards or regular expression strings.</li> <li>• The combination of the <b>Virtual Host</b> and <b>Context Root</b> must be unique. The following <i>is</i> allowed and incoming requests will match the most specific path first: <ul style="list-style-type: none"> <li>• vhost1:443/App</li> <li>• vhost1:443/App/Subpath</li> </ul> </li> <li>• /pa is, by default, reserved for PingAccess and is not allowed as a <b>Context Root</b>. You can change this reserved path using the PingAccess Admin API.</li> </ul>
Case Sensitive Path	No	Indicates whether or not to make request URL path matching case sensitive.
Virtual host(s)	Yes	Specifies the virtual host for the application. Click <b>Create</b> to create a virtual host.

Application Type	Yes	<p>Specifies the application type, either Web, API, or Web + API.</p> <ul style="list-style-type: none"> <li>If the <b>Application Type</b> is Web, specify whether or not you want to enable <b>SPA Support</b>. Select the <b>Web Session</b> if the application is protected and, if applicable, the <b>Identity Mapping</b> for the application. Click <b>Create</b> to create a Web Session or Identity Mapping.</li> <li>If the <b>Application Type</b> is API, specify whether or not you want to enable <b>SPA Support</b>. Indicate the method of <b>Access Validation</b> and, if applicable, select the <b>Identity Mapping</b> for the application. Click <b>Create</b> to create an Identity Mapping.</li> <li>If the <b>Application Type</b> is Web + API, specify whether or not you want to enable <b>SPA Support</b>. Indicate the method of <b>Access Validation</b>. Select the <b>Web Session</b> and, if applicable, the <b>Identity Mappings</b> to use for each type. In this configuration, the Web Session is required and the API is protected by default.</li> </ul>
Destination	Yes	<p>Specifies the application destination type, either Site or Agent.</p> <ul style="list-style-type: none"> <li>If the destination is a Site, select the <b>Site</b> requests are sent to when access is granted. If HTTPS is required to access this application, and at least one non-secure HTTP listening port is defined, select the <b>Require HTTPS</b> option. Click <b>Create</b> to create a Site.</li> <li>If the destination is an Agent, select the agent which intercepts and validates access requests for the Application. Click <b>Create</b> to create an Agent.</li> </ul>
Enabled	No	Select to enable the application and allow it to process requests.

### Editing an application

You can edit an existing application.

#### Steps

1. Navigate to **Applications**.
2. Expand the application on the **Properties** tab and click .
3. Make the required changes using [Manage Applications - Field Descriptions](#) as a guide.
4. Click **Save** or **Save and Go to Resources**.

### Deleting an application

You can delete an existing application.

#### Steps

1. Go to **Applications**.
2. Expand the application and click .
3. Click **Delete** to confirm.

### Application Resources

Application resources are components in an application that require a different level of security. You can manage security settings for application resources.

Choose from one of the following topics:

- [Resource ordering](#)
- [Path patterns](#)

### Resource ordering

Resources have one or more path patterns. When handling requests, PingAccess determines the path pattern that matches and associates the proper resource. When one or more path patterns matches a request, PingAccess uses the first matching pattern it identifies. As such, the order in which path patterns are evaluated is important.

By default, PingAccess orders path patterns automatically so that the most specific patterns are matched first. However, if more explicit control is needed, or if regular expressions are to be used, resource ordering can be enabled to manually specify the order in which path patterns are evaluated.

For example, an application may have three resources, such as:

- `/images/logo.png` (Basic)
- `/images/*` (Basic)
- `/.+/[a-z]\.png` (Regex)

A request to resource `/images/logo.png` is matched by all 3 path patterns, yet each resource may have different policy requirements. Resource ordering allows you to specify which of these path patterns is parsed first, further allowing you to control the policy that is applied to a particular request.

#### Enable resource ordering

To enable resource ordering, edit an existing application, navigate to the Resources tab, and click . Modify the resource order as necessary, then click **Save** to persist the changes.

#### Disable resource ordering

To disable resource ordering, you must first remove any Regex path patterns. Edit an existing application, navigate to the Resources tab, and click . Click **Disable manual ordering**.

#### Auto-order resources

When resource ordering is enabled, PingAccess can assist in the process by attempting to intelligently order resources based on their path patterns. While editing an application, navigate to the Resources tab, click , then click **Auto Order**. Modify the resource order as necessary, then click **Save** to persist the changes.

**Important:** The Auto Order function will reorder all resources for an application. You cannot undo this action, though you are able to re-order resources manually as appropriate.

### Path patterns

To allow for more flexible resource matching, PingAccess supports two types of path matching patterns, **Basic** and **Regex**.

**Note:** In order to specify a path pattern as **Basic** or **Regex**, you must enable **Resource Ordering**. When Resource Ordering is not enabled, all path patterns are assumed to be Basic, and are parsed as such.

#### Basic patterns

Basic path patterns (or “wildcard patterns”) are the default path pattern type. Each pattern defines a path to a specific resource or a pattern that matches multiple paths. Basic patterns may contain any number of “\*” wildcards, which match zero to many characters in the path.

For example, the Basic pattern:

```
/path/x/*
```

would match any of the following request paths:

```
/path/x/
/path/x/index.html
/path/x/y/z/index.html
```

### Regex patterns

Regex path pattern support is enabled when you enable resource ordering. Regex path patterns allow for more flexibility in resource matching. The supported syntax for regex patterns is that documented by the [RE2 wiki](#).

**Note:** When one or more regex path patterns are defined, resource ordering cannot be disabled. You must delete any regex path pattern entries before you can disable resource ordering.

For example, the Regex pattern:

```
/[^/]+/[a-z]+\.
```

would match any of the following request paths:

```
/images/gallery.html
/search/index.html
```

but would not match any of these paths:

```
/images/gallery2.html
/search/pages/index.html
/index.html
```

### Important: Use of regex path patterns in agent deployments

Though **Regex** path patterns will function in an agent deployment, a performance decrease may be incurred because the agent must consult PingAccess for policy decisions on all Regex path pattern resources.

In a deployment with **Basic** path patterns and resource ordering disabled, when a PingAccess agent receives a request for a resource, it consults its policy cache for policy decisions.

Agents are unable to interpret Regex path patterns, so a request to an agent for a resource with a Regex path pattern will result in the agent consulting PingAccess for each policy decision.

In a resource ordering scenario, the agent stops consulting its policy cache if it reaches a Regex path pattern, and continues this behavior for all resources ordered after the Regex path pattern resource, regardless of their type. Thus, the ordering of resources is critical to performance.

For example, consider the following scenario:

```
Application A: context root /, resource ordering enabled
Resource 1, Basic, /content
Resource 2, Regex, /\w+-\w+/.
Root Resource
```

If **Resource 2** is ordered before **Resource 1**, and a request for **Resource 1** is received by the agent, the agent will not leverage its policy cache, since a Regex path pattern disables caching for the associated resource and all resources after it.

If **Resource 1** is ordered before **Resource 2**, the agent will leverage its policy cache for requests to **Resource 1**.

The agent is only able to consult the policy cache for Basic path pattern resources that are ordered before any Regex path pattern resources. If a Basic path pattern resource is ordered after a Regex path pattern

resource, the agent will not consult the policy cache, instead contacting PingAccess directly, and thus a performance decrease may be incurred.

**Tip:** If you are using Regex path patterns in an agent deployment, and if the order in which resources are ordered is unimportant, Regex path patterns should be ordered at the end of the list. If the order is important, perhaps because a particular policy needs to be applied before others, place the resource where appropriate to ensure the correct policy is being applied at the correct time, while potentially incurring a performance impact.

If your deployment makes extensive use of agents and Regex path patterns, and you are experiencing performance problems, you might consider redeploying these applications in a proxy configuration where possible.

#### *Adding an application resource*

You can add an application resource to an existing application.

### Steps

1. Navigate to **Applications**.

2. Expand an application and click .

3. Click the **Resources** tab.

**Note:** A group containing all global unprotected resources is displayed on the first resources page. Review this list before adding a resource to ensure that there is no conflict between the new resource's path patterns and any unprotected resource path pattern.

4. To add a resource, click **Add Resource**.

**Info:** To edit a resource, expand the resource and click . To delete the resource, expand the resource and click .

5. Enter a unique **Name** up to 64 characters, including special characters and spaces.

6. Enter a list of URL path patterns (within the Context Root) that identify this resource. If [resource ordering](#) is enabled, select the path pattern type, **Basic** or **Regex**.

**Info:** The path pattern must start with a slash (/). It begins after the application context root and extends to the end of the URL.

- a. If automatic path pattern evaluation ordering is in use (default), patterns may contain one or more wildcard characters (\*). No use of wildcards is assumed, thus there is a difference between `/app/` and `/app/*`. If a request matches more than one resource, the most specific match is used.
- b. If manual path pattern ordering (resource ordering) is enabled, the use of regular expressions is permitted. When one or more path patterns contain a regular expression, you cannot revert to automatic path pattern ordering unless that path pattern is removed.

**Note:** If resource ordering is enabled, and you have specified a regular expression, ensure you select the **Regex** path pattern type. Failure to do so will cause the pattern to be interpreted incorrectly as a **Basic** text string.

**Note:** The application reserved path cannot be used as a path pattern when the context root is /. The default application reserved path is `/pa (/pa*)`. You can modify the default application reserved path using the PingAccess Admin API.

7. Select the type of **Resource Authentication**:

- Select **Standard** if the resource requires the same authentication as the root application.
- Select **Anonymous** if this resource has no authentication requirements. Identity mappings are still applied if the user is already authenticated. Access Control and Processing rules are applied where applicable.
- Select **Unprotected** if this resource has no authentication requirements. Processing rules are applied where applicable. No application or resource access control policy is applied.

**Note:** These options are not available for unprotected applications. **Web** applications types are unprotected when they do not have an associated web session. **API** applications are unprotected when they are not configured to be protected by an authorization server.

8. If the application type is **API** or **Web + API**, enter the **Methods** supported by the Resource. Leave the asterisk default if the Resource supports all HTTP methods, including custom methods. Defining Methods for a Resource allows more fine-grained access control policies on API Resources. For example, if you have a server optimized for writing data (POST, PUT) and a server optimized for reading data (GET), you may want to segment traffic based on the operation being performed.
9. Select the **Audit** checkbox to log information about the transaction to the audit store.
10. If the application type is **Web + API**, and **SPA Support** is disabled on the root application, indicate whether the application resource should override the fallback type specified for the main application. If you select **Yes** for this option, select the method to be used for the application resource when a request does not contain a web session cookie or OAuth token.

**Important:** It is important to carefully consider your configuration when making this selection. Changing the Application Fallback Type can have unexpected effects on Resources that do not override the Fallback. For example, if you configure a Web + API Application with a Fallback Type of Web along with several Resources that do not override the Fallback Type, these Resources will emit a 401 response (rather than a 302 to PingFederate) if you later change the Fallback Type to API on the main application. The PingAccess runtime uses Fallback Type to determine which processing flow (Web or API) to use when the request does not contain a web session or an API OAuth Bearer token. When a request does not contain either of these authentication mechanisms, it will rely on this configuration to determine which processing flow to use.

11. Select the **Enabled** check box to enable the resource.
12. Click **Save**.

#### *Applying rules to applications and resources*

You can apply rules, rule sets, and rule set groups to applications and resources. These changes are applied instantly.

#### **Steps**

1. Navigate to **Applications**.
2. Expand an application in the list and click .
3. Optional: To manage the policies for a resource, select the **Resources** tab, expand the resource you want to edit, and click .
4. Select the applicable tab. For **Web** applications, select the **Web Policy** tab. For **API** applications, select the **API Policy** tab. For **Web + API** applications, you can configure both **Web Policy** and **API Policy** on separate tabs, as required.
5. Using the radio selection, filter by [Rules](#), [Rule Sets](#), [Rule Set Groups](#), or **Rule Type**.
6. To create a new rule, click **Create Rule**.
7. To apply a rule, rule set, or rule set group, drag a rule from **Available Rules** onto the policy bar.
8. Drag items around in the box to change the order in which they are evaluated at runtime.

**Note:** Rule ordering can affect PingAccess performance; if an access control rule is more likely to reject access, it should appear near the top of the list to reduce the amount of processing that occurs before that rule is applied. This can be more noticeable if, for example, access control policies are applied along with processing rules. Applying your access control policies first ensures that no processing happens on responses unless the user is determined to be allowed access.

9. Click - next to an item to remove it from an application or resource.

#### **Global unprotected resources**

Global Unprotected Resources are resources that you specify as unprotected for all applications.

To specify a specific resource as unprotected for a single application, see [Application Resources](#) on page 174.

### Adding a global unprotected resource

You can create a new globally unprotected resource.

#### About this task

**Warning:** The following steps describe how to globally unprotect resources. Since any resource captured by the Wildcard Path of any entry is left unprotected **for all applications**, great care must be taken in planning these entries. To unprotect a resource for a specific application, see [Application Resources](#) on page 174.

#### Steps

1. Navigate to **Applications > Global Unprotected Resources**.
2. Click **+ Add Global Unprotected Resource**.
3. Enter a **Name** for the entry.
4. Optional: Enter a **Description** for the entry.
5. Optional: Select the **Audit Level** checkbox if you want to record access requests for this resource in the audit store.
6. Specify the **Wildcard Path** that identifies the Global Unprotected Resource. This entry must start with a slash (/) and may contain one or more wildcard characters (\*). Examples include:
  - /\*.jpg
  - /resources/\*.css
  - /\*/resources/favicon.ico

**Note:** Global Unprotected Resource paths are relative to the application context root. Reserved paths such as /pa, /pa/ or /pa/\* are allowed at the global level, but will not be evaluated for applications that are configured with a context root of /.

7. To enable the Global Unprotected Resource, select the **Enabled** checkbox.
8. Click **Save**.

### Editing a global unprotected resource

You can edit an existing global unprotected resource.

#### Steps

1. Navigate to **Main > Applications > Global Unprotected Resources**.
2. Expand the Global Unprotected Resource you want to edit and click .
3. Make the required changes.
4. Click **Save**.

### Deleting a Global Unprotected Resource

You can delete a global unprotected resource.

#### Steps

1. Navigate to **Main > Applications > Global Unprotected Resources**.
2. Expand the Global Unprotected Resource you want to delete and click .
3. Click **Delete** to confirm.

### Redirects

Redirects are used to redirect an incoming request to another target.

To configure a redirect, you map the host and port of an incoming request to that of a different target. At runtime, requests made to the **Source** will be redirected to the configured **Target**. This feature is useful in redirecting HTTP requests to an equivalent HTTPS URL.

Redirects are not associated with applications, but rather with the source:port combination you specify.

### Adding a redirect

You can add a new redirect.

#### Steps

1. Navigate to **Applications > Redirects**.
2. Click **+ Add Redirect**.
3. Specify the **Source** host and port that you want to redirect.
4. Specify the **Target** host and port that indicates the destination for the redirect.
5. Using the **Secure Target** check box, indicate whether or not the target is secure.
6. Specify the HTTP **Response Code** you want to associate with the redirect. 301 is specified as the default.
7. To audit redirects, select the **Audit** check box.

## Sites

The **Sites** tab contains controls for sites, site authenticators, and third-party services.

Choose from one of the following sections:

- [Sites](#) on page 180
- [Site Authenticators](#) on page 182
- [Third-Party Services](#) on page 185

### Sites

Sites are the target applications, endpoints, or APIs which PingAccess Gateway is protecting and to which authorized client requests are ultimately forwarded to.

#### Adding a site

You can add a site.

#### Steps

1. Navigate to **Sites > Sites**.
2. Click **Add Site**.
3. Complete the fields on the screen using [Site field descriptions](#) as a guide.
4. To configure advanced settings, click **Show Advanced**.
5. Click **Save**.

**Note:** If the target site cannot be contacted, the site is saved and a warning is displayed indicating the reason the site was not reachable.

#### Editing a site

You can edit the properties of an existing site.

#### Steps

1. Navigate to **Sites > Sites**.
2. Expand the site you want to edit, then click .
3. Make the required changes.
4. Click **Save**.

**Note:** If the target site cannot be contacted, the site is saved and a warning is displayed indicating the reason the site was not reachable.

### Deleting a site

You can delete an existing site.

### Steps

1. Navigate to **Sites > Sites**.
2. Expand the site you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm.

### Site field descriptions

This table describes the fields available for managing applications at **Sites > Sites**.

Field	Required	Description
Name	Yes	Enter a unique <b>Site Name</b> up to 64 characters, including special characters and spaces.
Targets	Yes	Specify one or more <b>Targets</b> . The format for this is <code>hostname:port</code> . For example, <code>www.example.com:80</code> .
Secure	Yes	Select <b>Secure</b> if the Site is expecting HTTPS connections. If the site is configured for <b>Secure</b> connections, select a <b>Trusted Certificate Group</b> from the list, or select <b>Trust Any</b> to trust any certificate presented by the listed targets.
Site Authenticators	No	If the Site requires the use of site authenticators, select one or more authenticators from the list. Click <b>Create</b> to create a Site Authenticator. Click <b>x</b> to remove a Site Authenticator.
Use Target Host Header	No	Select the check box to have PingAccess modify the <code>Host</code> header for the Site's Target Host and Target Port rather than the Virtual Host configured in the application.  <b>Note:</b> When cleared, PingAccess makes no changes to the <code>Host</code> header. This is often required by target web servers to ensure they service the HTTP request with the correct internal virtual server definition.
Skip Hostname Verification	No	To skip hostname verification, select the checkbox.
Expected Certificate Hostname	No	If you have not selected to skip hostname verification, enter the name of the host expected in the certificate in the <b>Expected Certificate Hostname</b> field. This field is available only if the <b>Skip Hostname Verification</b> checkbox is not selected. If left blank, the certificates will be verified using the target hostnames.
Availability Profile	No	Select an <a href="#">Availability profile</a> . Click <b>Create</b> to create an Availability Profile.
Load Balancing Strategy	No	Select a <a href="#">Load balancing strategy</a> if the site contains more than one target. Click <b>Create</b> to create a Load Balancing Strategy.

Send Token	No	<p>If your site uses the identity information in the PA Token or OAuth access token, leave this check box selected to include the token in the request to the back-end site.</p> <p>If you do not need the token information, you can clear the check box to remove the PA Token from the request. This excludes unnecessary information and decreases the payload size, which might improve performance.</p>
Maximum Connections	No	Enter the maximum number of HTTP persistent connections you want PingAccess to have open and maintain for the Site. A value of -1 indicates unlimited connections.
Maximum Websocket Connections	No	If the number of WebSocket connections needs to be limited, enter a value. The default of -1 indicates no limit.
Use Proxy	No	<p>Select if requests to the site should use a configured proxy.</p> <p><b>Note:</b> If the node is not configured with a proxy, requests are made directly to the site.</p> <p> <b>CAUTION:</b> If your proxy uses availability handling to retry multiple targets in the event of a network problem, PingAccess should be configured to use only one target for the site. Unexpected behavior could occur if PingAccess and the proxy are both configured to perform availability handling.</p>

### Site Authenticators

Site Authenticators define the authentication mechanism that target sites require to control access.

#### Adding a site authenticator

You can create a new site authenticator.

#### Steps

1. Navigate to **Sites > Site Authenticators**.
2. Click **Add Site Authenticator**.
3. Enter a unique **Name**.

**Note:** Special characters and spaces are allowed. This name appears in the **Site Authenticator** list on the **New Site** page.

4. Select the type of authentication from the list. Choose one of the following authentication types to continue.
  - [Basic authentication site authenticator](#)
  - [Mutual TLS site authenticator](#)
  - [Token mediator site authenticator](#)

#### Editing a site authenticator

You can edit the properties of an existing site authenticator.

#### Steps

1. Navigate to **Sites > Site Authenticators**.
2. Expand the site authenticator you want to edit, then click .
3. Make the required changes.
4. Click **Save**.

### Deleting a site authenticator

You can delete an existing site authenticator. A site authenticator cannot be deleted if it is associated with a site.

#### Steps

1. Navigate to **Sites > Site Authenticators**.
2. Expand the site authenticator you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm.

### Basic authentication site authenticator

Use HTTP Basic authentication (username:password) to authenticate a client requesting access to a site that requires basic authentication.

**Info:** Obtain the username and password from your target Site provider.

Field	Description
<b>Username</b>	The username required for access to the protected Site.
<b>Password</b>	The password required for access to the protected Site.

### Mutual TLS site authenticator

Use Key Pairs to authenticate PingAccess to a target Site. When initiating communication, PingAccess presents the client certificate from a Key Pair to the Site during the mutual TLS transaction. The Site must be able to trust this certificate in order for authentication to succeed.

**Tip:** Several setup steps are required for PingAccess certificate management before configuring the Mutual TLS Site Authenticator.

Field	Description
<b>Key Pair</b>	The imported/generated key pair for client authentication. Select the key pair you want to use to authenticate PingAccess to the target Site. To create a key pair, see <a href="#">Importing an existing key pair</a> on page 229 or <a href="#">Generating a new key pair</a> on page 229.

### Token mediator site authenticator

The token mediator site authenticator uses the PingFederate STS to exchange a PA Token for a security token, such as a WAM Token or OpenToken, that is valid at the target site.

**Note:** The token mediator site authenticator may benefit from the configuration of a PingAccess [Runtime State Cluster](#) to provide fault-tolerance for mediated tokens if a cluster node is taken offline.

Field	Description
<b>Token Generator ID</b>	Defines the Instance Name of the Token Generator that you want to use. The Token Generator is configured in <b>PingFederate</b> (see PingFederate documentation). If <a href="#">PingFederate Administration</a> is configured, and PingFederate has one or more token generators configured, this field becomes a list of available token generator IDs.

Field	Description
<b>Logged In Cookie Name</b>	Defines the cookie name containing the token that the target site is expecting.
<b>Logged Off Cookie Name</b>	Defines the cookie name that the target site responds with in the event of an invalid or expired token. If the PA Token is still valid, PingAccess re-obtains a valid WAM Token and makes the request to the site again. If the site responds with the cookie set as logged off again, PingAccess responds to the client with an access denied page.
<b>Logged Off Cookie Value</b>	Defines the value placed in the Logged Off Cookie to detect an invalid/expired WAM Token event.
<b>Source Token</b>	Defines the token type exchanged for a security token during identity mediation. Select <b>PA Cookie</b> for Web access or <b>OAuth Bearer Token</b> for API identity mediation.
<b>Send Cookies to Browser</b>	<p>Allows the Token Mediator to send the backend cookie defined in the <b>Logged In Cookie Name</b> field back to the browser if the protected application has updated it.</p> <p>If the set-cookie header isn't in the response from the protected site, and the Token Mediator Site Authenticator has a cached token for that session, the Token Mediator Site Authenticator will create a new set-cookie response header based on the <b>Cookie Domain, Cookie Max Age, HTTP-Only Cookie</b> and <b>Secure Cookie</b> fields in the UI.</p> <p>The admin now can direct the Token Mediator Site Authenticator to be an active player in returning cookies to the user's browser, even when the protected site isn't doing that.</p> <p>This could be used to enable a seamless SSO experience for users navigating from PingAccess protected applications to those protected by a 3rd party Web Access Management system.</p>
<b>Cookie Domain</b>	Enter the domain of the logged in cookie.
<b>Cookie Max Age</b>	Define the length of time in minutes, that you want the generated logged in cookie to be valid.
<b>HTTP-Only Cookie</b>	Define the logged in cookie as HTTP-Only. An HTTP-Only cookie is not accessible using non-HTTP methods, such as calls via JavaScript (for example, referencing document.cookie).
<b>Secure Cookie</b>	Indicate whether the generated logged in cookie must be sent using only HTTPS connections.

Field	Description
<b>Token Processor ID</b>	Defines the Instance Name of a Token Processor that you want to use. The Token Processor is configured in <b>PingFederate</b> (see PingFederate documentation). Specify this value if more than one instance of either the JWT Token Processor or the OAuth Bearer Access Token Processor is defined in PingFederate. If <a href="#">PingFederate Administration</a> is configured, and PingFederate has one or more token processors configured, this field becomes a list of available token processor IDs.

### Third-Party Services

A third-party service configuration defines the destination for HTTPS outbound calls. These definitions are used by custom plugins to indicate how the HTTP client will communicate with the destination.

The configuration of a third-party is similar to that of a site.

#### Adding a third-party service

You can add a new third-party service.

#### Steps

1. Go to **Sites > Third-Party Services**.
2. Click **+ Add Third-Party Service**.
3. Complete the fields on the screen using [Third-Party Service Field Descriptions](#) as a guide.
4. Click **Save**.

#### Editing a third-party service

You can edit the properties of an existing third-party service.

#### Steps

1. Go to **Sites > Third-Party Services**.
2. Expand the Third-Party Service you want to edit and click .
3. Make the required changes.
4. Click **Save**.

#### Deleting a third-party service

You can delete an existing third-party service.

#### Steps

1. Go to **Sites > Third-Party Services**.
2. Expand the Third-Party Service you want to delete and click .
3. Click **Delete** to confirm.

#### Third-Party Service Field Descriptions

The following table describes the fields available for managing applications at **Sites > Third-Party Services**.

Field	Required	Description
Name	<b>Yes</b>	Specify a name that identifies the third party service.
Targets	<b>Yes</b>	Specify one or more hostname:port pairs used to reach the third party service.

Secure	No	Indicate whether or not the target is expecting a secure connection.
Host Value	No	An optional value used as the Host header field value used in requests to a third party service regardless of the target used.
Skip Hostname Verification	No	For secure connections, select to indicate that the third-party service should not perform hostname verification of the certificate.
Expected Certificate Hostname	No	For secure connections, enter the name of the host expected in the certificate when hostname verification is enabled.
Availability Profile	<b>Yes</b>	Indicate the availability profile to use.
Load Balancing Strategy	No	Select the load balancing strategy to use if more than one target is defined.
Maximum Connections	<b>Yes</b>	Indicates the maximum number of HTTP persistent connections PingAccess will open and maintain for the service. The default of -1 indicates unlimited connections.
Use Proxy	No	Indicates that requests to the site should use a configured proxy.

## Agents

The **Agents** tab contains controls for managing agents. Agents are web server plugins that are installed on the web server hosting the target application, which intercept client requests to protected applications and allow or deny the request to proceed by consulting the Policy Manager or using cached information.

Agents communicate with the PingAccess Policy Server via the PingAccess Agent Protocol (PAAP) which defines in detail the possible interactions between agents and Policy Server. Agents have a name to identify them and a shared secret to authenticate with to Policy Server. Agents do not need to be unique. There can be any number of agents using the same name and secret and they are all treated equally by Policy Server. This is useful in complex deployments where unique agents would be difficult to manage. Agents can be assigned as the destination for one or more applications by name.

### Assigning an agent listener key pair

Before you create an agent, you must import or create an Agent listener key pair and assign it to the AGENT Listener.

#### Steps

1. Import or Generate a Key Pair. The key pair's subject or subject alternative names list need to include the host or hosts the agent will use to contact the PingAccess Policy Server.
2. Navigate to **Networking > Listeners > HTTPS Listeners**.
3. In the **AGENT** dropdown, select the Key Pair you want to use, and then click **Save**.
4. Restart PingAccess.

**Info:** If the environment is clustered, check the `pingaccess.log` file on each engine to ensure replication completed before restarting each engine.

### Adding an agent

You can create a new agent.

#### Steps

1. Navigate to **Agents > Agents**.
2. Click **Add Agent**.

3. Complete the fields on the screen using [Agent Field Descriptions](#) as a guide.
4. To configure advanced settings, click **Show Advanced**.
5. Click **Save & Download** to save the configuration and download `<agent-name>_agent.properties` for use with the PingAccess Agent.

**Note:** The **Shared Secret** is generated by PingAccess server and identified on this page with a timestamp. Existing secrets can be deleted by clicking the Remove button in the secret field. If an additional secret is needed, [edit](#) the agent and click **Save & Download** to generate and download a new Shared Secret.

**Note:** PingAccess can generate additional agent `agent.properties` files containing the specified information which can be used to configure the agent plugin. Existing configurations can also be re-downloaded if necessary.

### Editing an agent

You can edit an existing agent.

#### Steps

1. Navigate to **Agents > Agents**.
2. Expand an existing agent, then click .
3. Make the required changes.
4. To download the Shared Secret, click the **Download** button. To remove the Shared Secret, click the **Remove** button.
5. Click **Save & Download** to download the file.

### Deleting an agent

You can delete an existing agent.

#### Steps

1. Navigate to **Agents > Agents**.
2. Expand an existing agent, then click .
3. When prompted, click **Delete** to confirm.

### Agent Field Descriptions

The following table describes the fields available for managing applications at **Agents**.

Field	Required	Description
Name	Yes	Enter a unique alphanumeric <b>Name</b> for the agent, up to 64 characters.
Description	No	Enter an optional <b>Description</b> for the agent and its purpose.

PingAccess Host	Yes	<p>In the <b>PingAccess Host</b> fields, enter the <b>Hostname</b> and <b>Port</b> of the PingAccess server where the agent should send requests.</p> <p><b>Info:</b> The PingAccess Hostname and Port may not be the actual host and port that Policy Server is listening to, depending on network routing configuration and network elements such as reverse proxies and load balancers. The PingAccess Host and PingAccess Port are where the agent sends its requests. For example, if you have a cluster of engines behind a load balancer, the PingAccess Host and PingAccess Port values might point to the load balancer rather than directly to an engine host in order to provide fault tolerance for the agent connectivity.</p>
Failover Host	No	<p>In the <b>Failover Host</b> fields, enter the <b>Hostname</b> and <b>Port</b> of the PingAccess server where the agent should send requests in the event of a failover from the PingAccess Host.</p> <p><b>Tip:</b> Additional failover hosts may be added via API. For more information, see the <i>PingAccess API Management Guide</i>.</p>
Agent Trusted Certificate	Yes	<p>Specify the <b>Agent Trusted Certificate</b> to export in the agent properties file. The agent uses the selected certificate to communicate with the PingAccess engine via SSL/TLS. PingAccess gathers these certificates from imported certificates. If the appropriate certificate is not available, it needs to be <i>imported into the system</i>.</p> <p><b>Note:</b> You can specify the CA root certificate if the agent listener presents a CA-signed certificate chain.</p>
Override Request IP Source Configuration	No	<p>If required, select <b>Yes</b> to <b>Override Request IP Source Configuration</b> and enable additional controls that configure the agent to use different IP Source information.</p> <ul style="list-style-type: none"> <li>• Enter the <b>Header Names</b> used to identify the source IP address.</li> <li>• If more than one value is included in the <b>Header Names</b> field, use <b>List Value Location</b> to specify whether the first value or the last value in the list is used as the source address. The default value is <b>Last</b>.</li> <li>• Select <b>Fall Back to Last Hop IP</b> to use the last hop IP address as the source address when none of the listed <b>Header Names</b> are found. When this option is not selected, if none of the listed <b>Header Names</b> are found, access is denied and a <code>Forbidden</code> result is returned.</li> </ul>
Override Unknown Resource Configuration	No	<p>If required, select <b>Yes</b> to <b>Override Unknown Resource Configuration</b> to specify how requests for unknown resources should be handled. This mode is optional. If not set, the default agent mode will be used. Select a <b>Mode</b> to specify how requests for unknown resources should be handled, either <b>Deny</b> or <b>Pass-Through</b>.</p>
Max Retries	Yes	<p>Enter the <b>Max Retries</b> before considering a PingAccess server unavailable.</p>

Failed Retry Timeout	Yes	Enter, in seconds, the <b>Failed Retry Timeout</b> before retrying a failed PingAccess server.
----------------------	-----	------------------------------------------------------------------------------------------------

## Rules

The **Rules** tab contains controls for adding and managing rules. Rules let you specify who can access your applications and resources, how and when they can do so, and what modifications should be made to the requested content.

The Policy Manager is a rich drag-and-drop interface where you can manage policies by creating Rules, building Rule Sets and Rule Set Groups, and applying them to Applications and Resources. Policies are rules, set of rules, or groups of rule sets applied to an application and its resources. Policies define how and when a client can access target Sites. When a client attempts to access an application resource identified in one of the policy's Rules, Rule Sets, or Rule Set Groups, PingAccess uses the information contained in the policy to decide whether the client can access the application resource and whether any additional actions need to take place prior to granting access.

Access control rules can restrict access in a number of ways such as testing user attributes, time of day, request IP addresses, or OAuth access token scopes.

**Tip:** Ensure that any headers used in access control rules (such as `X-Forwarded-For`, which is used by Network Range rules) are sanitized and managed exclusively by inline infrastructure that users must be routed through before reaching PingAccess and the protected applications.

Processing rules can perform request processing such as modifying headers or rewriting URLs.

**Info:** Processing rules cannot be used with Agents.

Access control rules are applied before processing rules. For each type of rule, the rules are applied in the order configured in the user interface. All rules are evaluated after identity mappings, so rules have access to the request header field set by the identity mapping.

If rules for an application and rules for a resource both apply to a request, this order is used:

1. Application access control rules
2. Resource access control rules
3. Resource processing rules
4. Application processing rules

### Manage Rules

You can manage the rules that control access to your web apps and APIs.

### Configure advanced fields for rules

You can customize the action to take if policy evaluation fails. The default action is to use a [Rejection Handler](#) that defines whether to display an error template or redirect to a URL. To use a rejection handler, select it from the list.

With **Basic** rejection handling, you can customize an error message to display as part of the default error page rendered in the end-user's browser if Rule evaluation fails. This page is among the templates you can modify with your own branding or other information. Use the following fields, available in the **Advanced - Rejection Handling** section of a rule, to configure basic error handling.

Field	Description
<b>Error Response Code</b>	The HTTP status response code you want to send if Rule evaluation fails. For example, 403.
<b>Error Response Status Message</b>	The HTTP status response message you want to return if Rule evaluation fails. For example, Forbidden.

Field	Description
<b>Error Response Template File</b>	The HTML template page for customizing the error message that displays if Rule evaluation fails. This template file is located in the <code>PA_HOME/conf/template/</code> directory.
<b>Error Response Content Type</b>	The type of content for the error response so the client can properly display the response.

### Rule Creation

PingAccess supports a variety of rule types, and the procedures for rule creation are different for each rule type.

#### *Adding an authentication requirements rule*

The Authentication Requirements Rule is a PingAccess access control rule used to limit access to resources or applications protected by PingAccess based on the ACR values returned by the PingFederate Requested AuthN Context Authentication Selector. This allows authentication requirements to be applied when a policy decision is being made by the PingAccess Engine, allowing an entire application or individual resources to require a particular authentication type.

### Before you begin

#### Prerequisites:

- A PingFederate configuration that uses the Requested AuthN Context Authentication Selector.
- A configured authentication list.

### About this task

Use of this rule also allows for configurations that require more secure authentication methods. For example, a web site might allow a user to authenticate and view personal data using only a username and password, but editing their personal data could require an additional PingID verification step. When used in this manner, an additional step-up authentication event is automatically triggered.

**Tip:** When used in a rule set with `Any` criteria, this rule should be positioned first in the list to ensure step-up authentication is triggered upon rule set criteria failure.

### To configure an Authentication Requirements rule:

#### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Authentication Requirements**.
5. Select an [Authentication Requirements List](#).
6. Select a **Minimum Authentication Requirement**.

**Note:** The possible values for the **Minimum Authentication Requirement** are derived from the selected Authentication Requirements list.

7. Click **Save**.

### *Adding a Cross-origin Request rule*

You can add a Cross-origin request rule, which uses cross-origin resource sharing (CORS) to let a web server grant access to restricted resources (fonts, JavaScript, images, etc.) to an application served by another domain without granting access to those resources beyond a list of predefined origin servers.

#### **About this task**

Before a CORS request is sent, the originating web server generally sends a "pre-flight" `OPTIONS` request if the request from the client includes credentials. This pre-flight request is used to determine if the target server permits CORS requests to be processed from the originating web server.

PingAccess can be used to evaluate the headers provided in a CORS request to grant or deny access to resources.

**Note:** In addition to allowing PingAccess to evaluate the CORS request, you can also allow the request to be handled by the protected application, and let PingAccess be excluded from the process of evaluating the access request, if the target application type is `API`. In order to do this with a resource path that is protected by PingAccess and requires user authentication, configure a second resource with the same path pattern, but set the **Methods** field to `OPTIONS` and the **Anonymous** option needs to be cleared. This configuration allows the API request being made to be handled anonymously.

#### **To Configure a Cross-Origin Request Rule**

##### **Steps**

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Cross-Origin Request**.
5. Enter one or more **Allowed Origins** values, clicking to add additional values.

**Important:** While it is allowed, we recommend against using a value of `*` in this field. While this is a valid configuration, it is considered to be an insecure practice.

6. If additional options need to be configured, click **Show Advanced**.
7. To permit user credentials to be used in determining access, enable **Allow Credentials**.
8. To modify the **Allowed Request Headers** values, use the following options:
  - To add a new header, click **New Value**.
  - To edit an existing header, click the field and make your changes.
  - To remove an existing header, click .

The default headers are `Authorization`, `Content-Type`, and `Accept`.

9. To make specific response headers available to the client that originated the cross-origin request, enter the headers in the **Exposed Response Headers** field. Click **New Value** to add additional headers to the list.
10. To define the request methods allowed in cross-origin requests, select the desired overrides in the **Overridden Request Methods** field.
11. To modify the amount of time the pre-flight **OPTIONS** request is cached, enter the maximum age (in seconds) desired in the **OPTIONS Cache Max Age** field. The default is 600 seconds.
12. Click **Save**.

### *Rewrite rules overview*

It is sometimes necessary to manipulate requests to sites and their responses. PingAccess allows for the manipulation of the Request URI, the cookie domain, the cookie path, and three of the response headers (`Location`, `Content-Location`, and `URI`), as well as the response content.

For example, a site is hosted on `https://server1.internalsite.com/content/`. Users access the site via the following URL in their browser:

```
https://server1.internalsite.com/content/
```

For example purposes, let's say this results in a [302 Redirect](#) to an `importantContent.html` page as well as setting a domain cookie for `.internalsite.com`. If you protect this site with PingAccess (using the virtual host `publicsite.com`) under the application `/importantstuff/`, you need to rewrite the content. The information below discusses an example scenario.

**Info:** This example assumes that a virtual host, a site, and an application are already configured.

### Create a Rewrite Content rule

A Rewrite Content Rule alters content in the HTTP Response body.

- In the Response Content-Types field, you define a response type of `text/html`.
- In the Find and Replace criteria, you specify `<a href="https://server1.internalsite.com/content/">` and `<a href="https://publicsite.com/importantstuff/">`.
- Add the Rule to the application. A query to a page with links in it that point to `https://server1.internalsite.com/content/` now point to `https://publicsite.com/importantstuff/`.

### Create a Rewrite Cookie Domain rule

A Rewrite Cookie Domain Rule allows the rewriting of the Domain field on cookies when they are set by the back-end site.

- In the Server-Facing Cookie Domain, you enter `internalsite.com`.
- In the Public-Facing Cookie Domain, you enter `publicsite.com`.
- Add the Rule to the application.

Cookies associated with the domain `publicsite.com` (or `.publicsite.com`) are rewritten to pertain to `internalsite.com` (or `.internalsite.com`).

### Create a Rewrite Cookie Path rule

A Rewrite Cookie Path Rule converts the cookie path returned by the Site into a public-facing path.

- In the Server-Facing Cookie Path field, you enter `/content/`.
- In the Public-Facing Cookie Path field, you enter `/importantstuff/`.
- Add the Rule to the application.

Cookies associated with a cookie path of `/content/` are rewritten to pertain to `/importantstuff/`. After configuring the rewrite Rules as discussed above, a user could access the `https://publicsite.com/importantstuff/` and PingAccess would route that request to `https://server1.internalsite.com/content/`. If the Site sends a redirect to `https://server1.internalsite.com/content/index.html`, PingAccess would return a redirect to `https://publicsite.com/importantstuff/index.html`. If the Site then returned a cookie with a domain of `.internalsite.com` and a path of `/content/`, PingAccess would rewrite that cookie to be relevant to `.publicsite.com` and `/importantstuff/`.

### Create a Rewrite Response Header rule

A Rewrite Response Header Rule alters the response header used in the 302 Redirect.

- In the Server-Facing URI field, you enter `https://server1.internalsite.com/content/`.
- In the Public Path field, you enter `/importantstuff/`.
- Add the Rule to the application. A query resulting in a response containing a 302 Redirect to `https://server1.internalsite.com/content/` is rewritten to `https://publicsite.com/importantstuff/`.

**Info:** This also works for relative redirects: `/content/` is rewritten to `/importantstuff/`. It also works for the path beneath the one defined in the URI: `/content/news/index.html` is rewritten to `importantstuff/news/index.htm`.

### Create a Rewrite URL rule

A Rewrite URL Rule alters the Request URI.

- In the Map From field, you enter `^/importantstuff/(.*)` as the regex of the URL's path and query you want to match.
- In the Map To field, you enter `/content/$1`.
- Add the Rule to the application. A query to `https://publicsite.com/importantstuff/` results in PingAccess routing that query to `https://server1.internalsite.com/content/`.

### Adding a Rewrite Content rule

You can add a Rewrite Content rule, which modifies text in HTTP response bodies as it is served to the client.

### About this task

This rule uses a subset of the Java Regular Expression syntax that excludes look-behind constructs (for example, `\b`) and the boundary matcher (`\G`). If no Java regular expression syntax is used, the effect is to perform a case-sensitive search and replace. The most common use case for this rule is to rewrite host names within URLs contained in HTML, JavaScript or CSS content.

**Important:** While adding a Content Rewrite Rule in PingAccess 4.2, you cannot add a new row via the UI. Clicking the link to add a new row may cause page controls to become unresponsive. To work around this issue, use the API to create the rule or create multiple Content Rewrite Rules in the UI and combine them in a rule set.

**Info:** Extensive use of Rewrite Content Rules may have significant performance implications.

This rule supports content that is either chunked or streamed from the target server. When sent to the client, the content is always chunked.

### To configure a Content Rewrite rule:

#### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rewrite Content**.
5. Enter one or more **Response Content-Types** to define what type of response data the rewrite rule applies to. The default values are `text/html`, `text/plain`, and `application/json`. The list is an ordered list.

**Info:** Only text-based content types are supported. Text-based content types compressed with `gzip`, `deflate`, or `compress` will be decompressed prior to rewrite rule processing, however the content is not then re-compressed before being sent to the client.

6. Define one or more set of **Find and Replace Criteria**. If multiple criteria are specified, each operation is performed against the original content - effectively applying the rule concurrently.

**Important:** Changes can affect CSS, Javascript, and other text-based elements served to the client. Be sure to properly craft the regular expression to avoid modifying content that wasn't intended.

7. If necessary, increase the size of the buffer used to perform the replace operation by clicking **Show Advanced** and entering a value in **Maximum Buffer Size**.

**Note:** Replacement values cannot be larger than the buffer size. The minimum buffer size that can be specified is 1024 bytes; there is no maximum value.

8. If the protected application does not return a `Content-Type` header, select **Missing Content-Type Allowed**.
9. If **Missing Content-Type Allowed** is enabled, you must specify the encoding the application returns in the **Missing Content-Type Charset** field. For example, this field could contain `UTF-8`. A list of valid values is available in this [Oracle Java 8 SE Technical Note](#).
10. Click **Save**.

<b>Example</b>					
Examples:					
<b>Example description</b>	<b>Original content</b>	<b>Content-type</b>	<b>Find criteria</b>	<b>Replacement value</b>	<b>Modified text</b>
Rewrite URL portion of a web link	<code>&lt;a href="https://serverx.inside.acme.com/app/"&gt;</code>	<code>text/html</code>	<code>serverx.inside.acme.com</code>	<code>www.acme.com</code>	<code>&lt;a href="https://www.acme.com/app/"&gt;</code>
Case-sensitive text replacement	<code>ACMEcorp</code>	<code>text/html</code>	<code>Ecorp</code>	<code>E Corporation</code>	<code>ACME Corporation</code>
JSON Value masking	<pre>{   "origin":     "127.0.0.1,     192.168.1.1" }</pre>	<code>application/json</code>	<code>(127.0.0.1 192.168.1.1 *****)</code>	<code>*****</code>	<pre>{   "origin":     "127.0.0.1,     *****" }</pre>
Replacing text inside a specified element using Java regex groups	<code>This text is <b>bold</b>.</code>	<code>text/html</code>	<code>&lt;b&gt;(bold)&lt;/b&gt;</code>	<code>&lt;not \$1</code>	<code>This text is not bold.</code>
Case-insensitive text replacement using a Java regex match flag	<code>HTTP</code>	<code>text/html</code>	<code>(?i)http</code>	<code>FTP</code>	<code>FTP</code>

#### Adding a Rewrite Cookie Domain rule

You can add a Rewrite Cookie Domain rule, which converts the cookie domain returned by the site into a public-facing domain.

### About this task

For example, a Site places a cookie on a cookie domain such as `internalsite.com` (or `.internalsite.com`). Using the information configured in the Rewrite Cookie Domain Rule, PingAccess rewrites the `Domain` portion of the `Set-Cookie` response header with a public-facing domain such as `publicsite.com` (or `.publicsite.com`).

**Info:** You should only set the cookie (in the Public-Facing Cookie Domain field) to the virtual host name associated with that application or to a domain that is above. For example, `myserver.acme.com` can be set to `acme.com`.

### To configure a Rewrite Cookie Domain rule:

#### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rewrite Cookie Domain**.
5. If the target host needs to be explicitly defined, clear the **Any Site Target Host** checkbox.  
When the **Any Site Target Host** checkbox is enabled, PingAccess will rewrite the cookie domain if it is set to the domain defined in a site's target host list.
6. If **Any Site Target Host** is cleared, enter the domain name to used by the back-end site in the **Server-Facing Cookie Domain** field.
7. In the **Public-Facing Cookie Domain** field, enter the domain name you want to display in the response from PingAccess.
8. Click **Save**.

#### Adding a Rewrite Cookie Path rule

You can add a Rewrite Cookie Path rule, which converts the cookie path returned by the Site into a public-facing path.

### About this task

This enables the details of exposed applications to be managed by PingAccess for security and request routing purposes. For example, a Site places a cookie in a server-facing cookie path such as `/content/`. Using the information configured in the Rewrite Cookie Path Rule, PingAccess rewrites the `Path` portion of the `Set-Cookie` response header with a public-facing cookie path such as `/importantstuff/`.

### To configure a Rewrite Cookie Path rule:

#### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rewrite Cookie Path**.
5. In the **Server-Facing Cookie Path** field, enter the path name where the cookie is valid for the back-end Site.
6. In the **Public-Facing Cookie Path** field, enter the path name you want to display in the response from PingAccess.
7. Click **Save**.

#### Results

### Adding a Rewrite Response Header rule

You can add a Rewrite Response Header rule, which converts the response header value returned by the Site into a public-facing value.

#### About this task

This Rule rewrites one of three response headers: `Location`, `Content-Location`, and `URI`. For example, the server-facing `Location` response header includes a path that begins with `/test-war/`. Using the information configured in the Rewrite Response Header Rule, PingAccess rewrites `http://private/test-war/` with a public-facing path such as `http://public/path/`.

#### To configure a Rewrite Response Header rule:

##### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rewrite Response Header**.
5. If the target host needs to be explicitly defined, clear the **Any Site Target Host** checkbox.  
When the **Any Site Target Host** checkbox is enabled, PingAccess will rewrite the response header URI if it contains a domain defined in a site's target host list.
6. If **Any Site Target Host** is cleared, enter the domain name to used by the back-end site in the **Server-Facing URI** field.
7. In the **Public Path** box, enter a valid URI path that you want to write into the URI. This must be a valid URI path and begin and end with a slash ( `/` ). For example: `/importantstuff/` or `/`
8. Click **Save**.

### Adding a Rewrite URL rule

You can add a Rewrite URL rule, which examines the URL of every request and determines if a pattern matches.

#### About this task

For example, you define a regular expression (regex) in the rule. If a pattern matches, PingAccess uses the information configured in the Rewrite URL Rule and rewrites that portion of the URL into a path that the Site can understand. The following table displays four example Rewrite URL Rule configurations:

Map from value	Map to value	Example request	Rewrite by PingAccess
<code>/bank/</code>	<code>/application/</code>	<code>/bank/content.html</code>	<code>/application/content.html</code>
<code>^/bank/(.*)</code>	<code>/application/\$1</code>	<code>/bank/content.html</code>	<code>/application/content.html</code>
<code>/bank/index.html</code>	<code>/application/index.jsp</code>	<code>/bank/index.html</code>	<code>/application/index.jsp</code>
<code>/bank/index.html</code>	<code>/application/index.jsp</code>	<code>/bank/index.html?query=stuff</code>	<code>/application/index.jsp?query=stuff</code>

#### To configure a Rewrite URL rule:

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rewrite URL**.
5. In the **Map From** box, enter the regex of the URL's path and the query you want to match. For example: `^/bank/(.*)` This example illustrates matching the `Request-Line` in the request. The `Request-Line` begins with `/bank/` (the `^` indicates "begins with") and places the rest of the URL into the first capture group (for more information on regex patterns, see the [Oracle Java Docs](#)).
6. In the **Map To** box, enter the URL's path and query you want to generate. For example: `/application/$1` This example defines the replacement string, which generates `/` followed by the content of the first capture group (to better understand the use of special characters such as `\` and `$` in the replacement string, see the [Oracle Java Docs](#)).
7. Click **Save**.

### *Adding a Groovy script rule*

You can add a Groovy script rule, which provides advanced rule logic that extends PingAccess rule development beyond the capabilities of the packaged [Policy Manager](#) rules.

## About this task

**Note:** Through Groovy scripts, PingAccess administrators can perform sensitive operations that could affect system behavior and security. Please note that since the regular Groovy Rule and the OAuth Groovy Rule differ in the scope of their functionality, the relevant rules are tagged for Web App or for API, respectively, in the rules dropdown menu.

See [Advanced Fields](#) for information about error handling.

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Groovy Script (for Web App)**.
5. Enter the Groovy Script to use for Rule evaluation. For example, to create an OAuth Scope Rule that matches more than one scope, your Groovy script might contain:
 

```
hasScopes("access", "portfolio")
```
6. If you need to configure error handling parameters, click **Show Advanced** to provide those configuration options.
7. Click **Save** when you finish.

### *Adding an HTTP Request Header rule*

You can add an HTTP Request Header rule, which examines a request and determines whether to grant access to a requested resource based on a match found in one of the specified headers in the HTTP request.

## About this task

**Note:** See [Advanced Fields](#) for information about error handling.

If more than one **Field** and **Value** pair is listed, then all conditions must match in order for the rule to succeed.

**To configure an HTTP Request Header rule:**

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **HTTP Request Header**.
5. In the **Field** column, enter a **Header** name you want to match in order to grant or not grant the client access.
6. Enter the **Value** for the Header you want to match in order to grant or not grant the client access. The wildcard (\*) character is supported.

**Tip:** If you want to match on the `Host` header, include both the host and port as the **Value**, or add a wildcard after the hostname (`host*` or `host:*`) to match what is in the HTTP request.

7. Select **Case Sensitive** if the values should be matched only if the value case is an exact match.
8. Select **Negate** if access should be denied when a match is found.

**Info:** Ensure that the attribute name entered in the **Field** field is spelled correctly and exists. If you enter an attribute that does not exist and you select **Negate**, the rule will always succeed. The **Negate** control applies to the entire set of conditions specified, and passes the rule if any condition is not met.

9. If additional **Header** pairs are needed, click **Add Row** to add an additional row, then repeat steps 1-4.
10. If you need to configure error handling parameters, click **Show Advanced** to provide those configuration options.
11. Click **Save**.

### *Adding an HTTP Request Parameter rule*

You can add an HTTP Request Parameter rule, which examines a request and determines whether to grant access to a requested resource based on a match found in specified form parameters of the HTTP request.

## About this task

This rule determines if the parameters are passed as part of the URL query string parameters or as part of a request body submitted using an HTTP PUT or POST method. If the request is a POST request, the `content-type` must be set to `application/x-www-form-urlencoded` to process the field names in the request.

If this rule is applied to an Agent configuration, only URL query string parameters are compared, because the Agent does not receive the request body for processing.

If more than one **Field** and **Value** pair is listed, then all conditions must match in order for the rule to succeed.

**Note:** See [Advanced Fields](#) for information about error handling.

### To configure an HTTP Request Parameter rule:

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **HTTP Request Parameter**.
5. In the **Field** column, enter a **Parameter** name you want to match in order to grant or not grant the client access.

6. Enter the **Value** for the field you want to match in order to grant or deny the client access. The wildcard (\*) character is supported.

**Note:** Values entered here will be URL-encoded prior to the comparison. For example, if the value specified in the **Value** field is `v1 v2`, when the engine performs the comparison, this value will be converted to `v1%20v2` before the search is performed.

7. Select **Case Sensitive** if the values should be matched if the value case is an exact match.
8. Select **Negate** if when a match is found, access is not allowed.

**Info:** Ensure that the field name you enter is spelled correctly and exists. If you enter a field name that does not exist and you select **Negate**, the rule will always succeed. The **Negate** control applies to the entire set of conditions specified, and passes the rule if any condition is not met.

9. If additional **Parameters** pairs are needed, click **Add Row** to add an additional row, then repeat steps 1-4.
10. If you need to configure error handling parameters, click **Show Advanced** to provide those configuration options.
11. Click **Save**.

#### *Adding a Network Range rule*

You can add a Network Range rule, which examines a request and determines whether to grant access to a target Site based on whether the IP address falls within a specified range (using Classless Inter-Domain Routing notation).

#### **Steps**

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Network Range**.
5. Enter a **Network Range** in the field. For example, `127.0.0.1/8`. PingAccess supports both IPv4 and IPv6 addresses.
6. Select **Negate** if when a match is found, access is not allowed.
7. If you wish to override source address handling defined in the **HTTP Requests** configuration, click **Show Advanced** and perform the following steps:
  - a) Select the **Override Request IP Source Configuration** option.
  - b) Enter the **Headers** used to define the Source IP address to use.
  - c) Select the **Header Value Location** to use when multiple addresses are present in the specified header. Valid values are `Last` (the default) and `First`.
  - d) Select the **Fall Back to Last Hop IP** option to determine if, when the specified **Headers** are not present, PingAccess should return a `Forbidden` result or if it should use the address of the previous hop as the source to make policy decisions.
8. Additional advanced fields for handling error responses may also be defined here. See [Advanced Fields](#) for more information about these fields.
9. Click **Save**.

#### *Adding an OAuth Attribute Value rule*

You can add an OAuth Attribute Value rule, which examines a request and determines whether to grant access to a target Service based on a match found between the attributes associated with an OAuth access token and attribute values specified in the OAuth Attribute Rule.

#### **Steps**

1. Navigate to **Rules > Rules**.

2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **OAuth Attribute**.
5. Select an **Attribute Name** you want to match to an attribute associated with an OAuth access token.
6. In the **Attribute Value** box, enter the value to match.

**Note:** The attribute values come from the contract in your OAuth access token manager in PingFederate. See [Defining the Access Token Attribute Contract](#) for more information.

7. Add additional rows of attribute name/value pairs as needed.

**Note:** If multiple rows are included here, all conditions must match in order for the rule to match.

8. Select **Negate** if when a match is found, access is not allowed.

**Info:** Verify what you enter for the attribute. If you enter an attribute that does not exist (for example, misspell it) and you select **Negate**, the rule will always succeed.

9. Click **Save**.

#### *Adding an OAuth Groovy Script rule*

You can add an OAuth Groovy Script rule, which determines whether to grant access to a target Site based on the results returned from a Groovy script that evaluates request details and OAuth details.

#### **About this task**

This rule allows you to create more sophisticated OAuth Scope and OAuth Attribute Value Rules for API applications.

**Info:** Please note that since the regular Groovy Rule and the OAuth Groovy Rule differ in the scope of their functionality, the relevant rules are tagged for Web App or for API, respectively, in the UI's rules dropdown menu.

#### **To configure an OAuth Groovy Script rule:**

##### **Steps**

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **OAuth Groovy Script (for API)**.
5. Enter the **Groovy Script** to use for Rule evaluation.
6. If you need to specify a custom Error Response Template File, click **Show Advanced** and fill in the **Error Response Template File** and **Error Response Content Type** fields.
7. Click **Save**.

##### **Results**

See [Advanced Fields](#) for information about error handling.

#### *Adding an OAuth Scope rule*

You can add an OAuth Scope rule, which examines the contents of the PingFederate validation response and determines whether to grant access to a back-end target Site based on a match found between the scopes of the validation response and scope specified in the OAuth Scope Rule.

#### **About this task**

For example, a Resource may require that the OAuth Access Token contain the scope `superuser`.

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **OAuth Scope**.
5. Select the **Scope** you want to match to values returned from the access token.  
**Info:** This is one scope requirement in the set of scopes associated with the access token.
6. Select **Negate** if when a match is found, access is not allowed.
7. Optional: If you want to use a customized error response template, click **Show Advanced** and provide the **Error Response Template File** and **Error Response Content Type** values.
8. Click **Save**.

### *Adding an OAuth Token Cache Time To Live rule*

You can add an OAuth Token Cache Time to Live rule, which configures the caching behavior for access tokens.

## About this task

This rule allows the global OAuth token cache configuration to be selectively overridden for specific applications or resources.

### To configure an OAuth Token Cache Time To Live rule:

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **OAuth Token Cache Time to Live**.
5. Specify whether you want to cache the introspection of access tokens.
6. Specify the number of seconds to cache the introspection of the access token. This value should be less than the token provider's token lifetime. A value of -1 means no limit.
7. Click **Save**.

### *Adding a Rate Limiting rule*

You can add a Rate Limiting rule, which lets you limit a client from overloading the server with too many requests in a specified period of time.

## About this task

The implementation of this rule uses a *Token Bucket* in order to control the number of incoming requests.

**Note:** The rate limiting rule may benefit from the configuration of a PingAccess [Runtime State Cluster](#) to ensure rate limits are enforced properly if the front-end load balancer does not provide a sticky session.

The way this works is that the configuration defines a number of requests and an interval that must elapse between requests. The allowed number of requests within the time window is controlled by the **Max Burst Requests** setting visible when you click **Show Advanced**. For example, if the **Max Burst Requests** value is 1, two requests are allowed in the request interval — one normal request, and one burst request.

The number of allowed requests is incremented by one at the end of each **Request Interval** if a request was not received. This continues until the number of allowed requests equals the value defined by the **Max Burst Requests** setting.

**Note:** Using the Rate Limiting Rule in a clustered PingAccess environment may impose stricter clock synchronization requirements for requests processed by multiple engine nodes. Alternatively, a load balancer sitting in front of a PingAccess cluster can be configured to stick the session to a specific engine, thus ensuring that the rate limiting rule is applied by a single PingAccess engine node.

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rate Limiting**.
5. Select a **Policy Granularity**, as defined in the following table:

Policy Granularity	Definition
Resource	Restricts the rate of requests based on the resource requested.
Identity	Restricts the rate of requests to the identity associated with the current authentication token (a PA Cookie or an OAuth token). This is the default value.
IP	Restricts the number of requests based on the source IP address. The IP address used to apply this policy comes from the HTTP Requests IP Source configuration options or options that override that configuration, if those options are configured.
OAuth Client	Restricts the number of requests to all OAuth tokens obtained by a specific <b>Client ID</b> .

6. Enter, in milliseconds, a **Request Interval**.
7. If more than 1 request should be allowed a request interval, expand the **Advanced** section of the page, and enter the number of requests to allow in the **Max Burst Requests** field.

**Note:** PingAccess increases the number of available requests only after a request interval that serves no requests to the client. As a result, in the period following a cycle where the remaining allowed burst requests is reduced to 0, no burst requests would be allowed, regardless of this setting.

8. If PingAccess should reply to the client with a `Retry-After` header instructing the client to wait for a period of time, select the **Set Retry-After Header** option.
9. To customize the error response sent to the client, click **Show Advanced** and modify the **Error Response Code**, **Error Response Status Message**, **Error Response Template File**, and **Error Response Content Type** fields. See [Advanced Fields](#) for more information about these fields.
10. Click **Save**.

### *Adding a Redirect rule*

You can add a Redirect rule, which specifies a fixed URL that a user agent should request in response to being denied access to the requested resource.

## About this task

Redirect rules can be applied to one or more applications.

### To configure a Redirect rule:

### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Redirect**.
5. Specify the **Response Status Code** you want to associate with the redirect. The default is 302.
6. Specify the **URL** to which you want to redirect requests. URLs must include the `http/https` prefix. The URL can be specified with or without defining the port.
7. Click **Save**.

#### *Adding a Rejection rule*

You can add a rejection rule, which specifies an action to take when a request to an application or resource is rejected by policy evaluation.

### About this task

A rejection rule uses [Rejection Handlers](#) to define which action you want to take, either rejecting the request and displaying an error template, or redirecting the user to another URL for error details, instructions, or additional actions.

To configure a **Rejection** rule:

### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Rejection**.
5. Specify the **Rejection Handler** you want to use for the rule.
6. Click **Save**.

#### *Adding a Time Range rule*

You can add a Time Range rule, which examines a request and determines whether to grant access to a back-end target site based on the request falling within a defined time frame.

### About this task

For example, use this Rule when you want to restrict access to specific endpoints for certain time periods, such as during the work day from 8 am to 5 pm.

To configure a **Time Range** rule:

### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Time Range**.
5. Enter the beginning time for the time frame in the **Start Time** field. For example: 8:00 AM.
6. Enter the ending time for the time frame in the **End Time** field. For example: 5:00 PM.

**Info:** If you are using Internet Explorer or Firefox, you must enter the time in 24 hour format. For example, 5:00 PM is 17:00.

7. Select **Negate** if when a match is found, access is not allowed.
8. Click **Save** when you finish.

## Results

See [Advanced Fields](#) for information about error handling.

### *Adding a Web Session Attribute rule*

You can add a Web Session Attribute rule, which examines a request and determines whether to grant access to a target Site based on an attribute value match found within the PA Token.

## Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Web Session Attribute**.
5. Select the **Attribute Name** that you want to match in order to grant the client access. For example, `Group`.
6. Enter the **Attribute Value** for the Attribute Name. For example, `Sales`. If the attribute has multiple values at runtime, the attribute value you specify here must match one of those values.

**Info:** PA Token attributes are obtained from the PingFederate OpenID Connect Policy attribute contract (see [Configuring OpenID Connect Policies](#)).

7. Click **Add Row** to add more attributes, or click  to remove a row.
8. Select **Negate** to disallow access when a match is found.

**Info:** Ensure the attribute name is spelled correctly and exists. If you enter an attribute that does not exist and you select **Negate**, the rule will always succeed.

9. Click **Save**.

## Results

**Info:** To use this rule, we recommend that you leave the **Request Profile** checkbox selected, indicating that you want PingAccess to request additional profile attributes from PingFederate when requesting the ID Token.

See [Advanced Fields](#) for information about error handling.

### *Adding a Web Session Scope rule*

You can add a Web Session Scope rule, which examines the contents of the PingFederate validation response and determines whether to grant access to a back-end target site based on a match found between the scopes of the validation response and scope specified in the Web Session Scope Rule.

## About this task

For example, a Resource may require that the Access Token contain the scope `superuser`.

To configure PingFederate to support this rule:

1. [Enable Expressions](#).
2. [Extend the Access Token Attribute Contract](#) to include the value `scope`.
3. Map the following value into the [access token attribute contract](#):

Contract	Source	Value
scope	Expression	@com.pingidentity.sdk.oauth20.Scope@encod

4. Manage the *OpenID Connect policy* to add the following information:

- *Attribute Contract* - Extend the contract to include the `scope` attribute. Choose to **Override Default Delivery** using the **ID Token**.

**Note:** This step is not applicable to PingFederate 9.0 and earlier. Instead, on the **Manage Policy** screen, select the check box to **Include User Info in ID Token**.

- *Attribute Scopes* - Associate the `openid` **Scope** with the `scope` **Attribute**.

**Note:** This feature does not exist in PingFederate versions prior to 9.0. To work around this issue:

- Ensure PingAccess is configured to include `profile` in the list of Web Session scopes.
- In PingFederate, ensure the `profile` scope is defined in *Scope Management*.
- During authentication, the user must accept usage of the `profile` scope. If the user does not accept usage of profile scope then the Web Session Scope rule will always fail for that user.

- *Contract Fulfillment* - Modify the `scope` **Attribute Contract** to use `Access Token` as the **Source** with a **Value** of `scope`.

#### To configure a Web Session Scope rule:

##### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **Web Session Scope**.
5. Select the **Scope** you want to match to values returned from the access token.

**Info:** This is one scope requirement in the set of scopes associated with the access token.

6. Specify the **Rejection Handler** you want to associate with this rule.
7. Click **Save**.

##### *Adding a WebSocket Handshake rule*

You can add a WebSocket handshake rule, which lets you define the domains that can open a cross-origin WebSocket to the application or resource.

#### About this task

You can also define allowed WebSocket subprotocols and extensions, providing more fine-grained control over how the application behaves.

#### To configure a WebSocket Handshake rule:

##### Steps

1. Navigate to **Rules > Rules**.
2. Click **+ Add Rule**.
3. Enter a unique **Name**. The name can be up to 64 characters long. Special characters and spaces are allowed.
4. In the **Type** dropdown, select **WebSocket Handshake**.
5. Enter one or more **Allowed Origins**. If no origins are defined, all cross-origin WebSocket requests are denied.

**Important:** While it is allowed, we recommend against using a value of \* in this field. While this is a valid configuration, it is considered to be an insecure practice.

6. Modify the list of **Allowed Subprotocols**. Subprotocols are defined in the `Sec-WebSocket-Protocol` handshake header. The default value of \* allows all subprotocols.
7. Modify the list of **Allowed Extensions**. WebSocket extensions are defined in the `Sec-WebSocket-Extensions` handshake header. The default value of \* allows all extensions.
8. Click **Save**.

## Results

See [Advanced Fields](#) for information about error handling.

## Editing a rule

You can edit the properties of an existing rule.

## Steps

1. Navigate to **Rules > Rules**.
2. Expand the rule you want to edit and click .
3. Make the required changes.
4. Click **Save**.

## Deleting a rule

You can delete an existing rule.

## Steps

1. Go to **Rules > Rules**.
2. Expand the rule you want to delete and click .
3. When prompted, click **Delete** to delete the rule.

## Manage Rule Sets

Rule sets let you combine rules into reusable groupings.

### Adding a rule set

You can add a new rule set.

## Steps

1. Go to **Rules > Rule Sets**.
2. Click **+ Add Rule Set**.
3. Drag a Rule from the **Rules** column onto the box that appears.
4. Enter a name for the Rule Set in the box that appears. Special characters and spaces are allowed.
5. Select **All** as the **Success Criteria** to require all Rules in the set to succeed. Select **Any** to require just one of the Rules in the set to succeed.

**Info:** When **Success Criteria** is set to **Any**, the first rule establishes the error handling and is flagged with a tooltip that displays a message indicating that. When **Success Criteria** is set to **All**, the first rule in the set that fails establishes the error handling.

**Note:** When **Success Criteria** is set to **Any**, PingAccess flags Processing Rules in a Rule Set with tooltip that warns that if the first rule in the list succeeds, additional rules will not be processed. This is considered a misconfiguration because in an **Any** Rule Set, the first Processing Rule should succeed, causing all other rules in the set to not be evaluated. If you want to use Processing Rules on protected

applications as well as handle access control decisions using **Any** criteria, assign Processing Rules directly to the application or create a separate Rule Set for the Processing Rules using the **All** criteria."

6. Click **Save** to save the Rule Set.
7. Add more Rules.

### Editing a rule set

You can edit an existing rule set.

### Steps

1. Navigate to **Rules > Rule Sets**.
2. Expand the rule set you want to edit. Choose from:
  - Drag a rule within a rule set up or down to re-order the rules.
  - Click - to the right of any rule you want to remove from a rule set.
  - Click to delete the rule set.
  - Click to edit the rule set **Name** or **Success Criteria**.
3. Click **Save** after changing these values.

### Deleting a rule set

You can delete an existing rule set. You must remove any associations between the rule set and any applications or resources before you can delete it.

### Steps

1. Navigate to **Rules > Rule Sets**.
2. Expand the rule set you want to delete.
3. Click .
4. When prompted, click **Remove** to confirm the delete request.

### Manage Rule Set Groups

Rule set groups let you combine one or more rule sets into reusable groups.

#### Adding a rule set group

You can add a new rule set group.

### Steps

1. Navigate to **Rules > Rule Set Groups**.
2. Click **+ Add Rule Set Group**.
3. Drag a Rule Set from the **Rule Sets and Groups** column onto the box that appears.
4. Enter a name for the Rule Set Group in the box that appears. Special characters and spaces are allowed.
5. Select **All** as the **Success Criteria** to require all Rules in the set to succeed. Select **Any** to require just one of the Rules in the set to succeed.

**Info:** When **Success Criteria** is set to **Any**, the first rule set establishes the error handling and is flagged with a tooltip that displays a message indicating that. When **Success Criteria** is set to **All**, the first rule in the set that fails establishes the error handling.

**Note:** When **Success Criteria** is set to **Any**, PingAccess flags Processing Rules in a Rule Set Group with tooltip that warns that if the first rule in the list succeeds, additional rules will not be processed. This is considered a misconfiguration because in an **Any** Rule Set Group, the first Processing Rule should succeed, causing all other rules in the set to not be evaluated. If you want to use Processing Rules on protected applications as well as handle access control decisions using **Any** criteria, assign Processing

Rules directly to the application or create a separate Rule Set Group for the Processing Rules using the **All** criteria."

6. Click **Save** to save the Rule Set Group.
7. Add more rule sets or rule set groups.
8. Configure rule set hierarchy by dragging rule sets in the rule set group. Processing occurs from top to bottom. The configuration is automatically saved.

### Editing a rule set group

You can edit the properties of an existing rule set group.

#### Steps

1. Navigate to **Rules > Rule Sets and Groups**.
2. Expand the rule set group you want to edit. Chose from:
  - Drag a rule set within a rule set group up or down to re-order the rules.
  - Click - to the right of any rule set you want to remove from a rule set group.
  - Click to delete the rule set group.
  - Click to edit the rule set group **Name** or **Success Criteria**.
3. Click **Save** after changing these values.

### Deleting a rule set group

You can delete an existing rule set group. You must remove any associations between the rule set group and any applications or resources before you can delete it.

#### Steps

1. Go to **Rules > Rule Set Groups**.
2. Expand the rule set group you want to delete.
3. Click .
4. When prompted, click **Remove** to confirm.

### Manage Rejection Handlers

A rejection handler defines the action to take when a request to an application or resource is rejected by policy evaluation. This lets you decide if you want to display an **error template** or **redirect** the user to another URL for error details, instructions, or additional actions.

You can specify the response status code that you want to send if policy evaluation fails.

You include a rejection handler in a rule by expanding the **Advanced** section of the **Create Rule** screen.

PingAccess contains 3 predefined rejection handlers:

- Default API Rejection Handler – Returns a 403 status code in a JSON template
- Default Rate Limiting Rejection Handler – Returns a 429 status code in a JSON template
- Default Web Rejection Handler – Returns a 403 status code in HTML template

### Creating a rejection handler

You can create a new rejection handler.

#### Steps

1. Navigate to **Rules > Rejection Handlers**.
2. Click **+ Add Rejection Handler**.
3. Specify a **Name** for the object.

#### 4. Choose the **Type**, **Error Template** or **Redirect**.

- If you selected Error Template, specify the **Response Status Code**, the **Template File**, and the **Content Type**.
- If you selected Redirect, specify the **Response Status Code**, and **URL** to which you want to redirect if policy evaluation fails.

#### **Editing a rejection handler**

You can edit the properties of an existing rejection handler.

#### **Steps**

1. Go to **Rules > Rejection Handlers**.
2. Expand the rule you want to edit and click .
3. Make the required changes.
4. Click **Save**.

#### **Deleting a rejection handler**

You can delete an existing rejection handler.

#### **Steps**

1. Go to **Rules > Rejection Handlers**.
2. Expand the rule you want to delete and click .
3. When prompted, click **Remove** to delete the rule.

## **Access**

The **Access** tab contains controls for authentication requirements, identity mappings, virtual hosts, web sessions, and unknown resources.

Choose from one of the following sections:

- [Authentication requirements](#) on page 209
- [Identity Mappings](#) on page 210
- [Virtual Hosts](#) on page 213
- [Web Sessions](#) on page 215
- [Unknown Resources](#) on page 219

#### **Authentication requirements**

Authentication requirements are policies that dictate how a user must authenticate before access is granted to a protected Web Application.

Authentication methods are string values and ordered in a list by preference. At runtime, the type of authentication attempted is determined by the order of the authentication methods.

For example, a user attempts to access a PingAccess Web Application configured with an authentication requirement list containing the values (password, cert). PingAccess redirects the user to PingFederate requesting either password or certificate user authentication. PingFederate authenticates the user based on the password and issues an OIDC ID Token to PingAccess (containing the authentication method that was used). PingAccess ensures that the authentication method matched the requirements and redirects the user to the originally requested Application with the PA cookie set. The user navigates to the Application and access is granted. When the user attempts to access a more sensitive Application, configured with an authentication requirement list containing the value (cert), they are redirected to PingFederate to authenticate with a certificate.

If you configure Applications with authentication requirement lists that have no overlap. For example, one list has (password), another list (cert), a user navigating between Applications may be required

to authenticate each time they visit an Application. When configuring authentication requirement lists to protect higher value Applications with step-up authentication, consider including stronger forms of authentication when configuring lower value Applications.

### Configuring an authentication requirements list

You can configure a list of authentication requirements.

#### Steps

1. Navigate to **Access > Authentication Requirements**, and click **Add Authentication Requirement**.
2. Enter a unique name for the Authentication Requirements list.
3. Enter an authentication method. For example, `cert` or `password`.

**Info:** The values you enter here must match the result values defined for the Requested AuthN Context Selector configured within PingFederate (see [Configuring the Requested AuthN Context Selector](#)).

4. Click **Add Authentication Requirement** to add additional authentication requirements.
5. Click **Save**.

### Editing an authentication requirements list

You can edit the properties of an existing authentication requirements list.

#### Steps

1. Navigate to **Access > Authentication Requirements**.
2. Expand list you want to edit, then click .
3. Make your changes.
4. Click **Save**.

### Deleting an authentication requirements list

You can delete an existing authentication requirements list.

#### Steps

1. Navigate to **Access > Authentication Requirements**.
2. Expand the authentication requirement you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm.

### Identity Mappings

Identity mappings make user attributes available to back-end sites that use them for authentication. There are multiple types of identity mappings, each with different behavior and a distinct set of fields to specify the identity mapping behavior.

#### Configuring Auth Token Management

You can configure auth token management to define the issuer and signing configuration used by JWT Identity Mappings.

#### Steps

1. Navigate to **Access > Identity Mappings**.
2. Specify the **Key Roll Interval (h)** to indicate how often (in hours) you want to roll the keys. Key rollover updates keys at regular intervals to ensure the security of the signed auth tokens.
3. Specify a published, unique **Issuer** identifier to be used with auth tokens. For example, set the issuer to a value that more closely represents your company. PingAccess inserts this value as the `iss` claim within the auth tokens.

4. Specify the **Signing Algorithm** used to protect the integrity of the auth tokens (the default is ECDSA using P-256 Curve).
5. Click **Save**.

### Creating a header identity mapping

You can create a header identity mapping to make user attributes or client certificates available as HTTP request headers to applications, both site and agent based, that use them for authentication.

#### About this task

A single Header identity mapping can expose a number of attribute values or a certificate chain up to 3 levels deep. Header identity mappings are assigned to applications.

#### Steps

1. Navigate to **Access > Identity Mappings**.
2. Click **+ Add Identity Mapping**.
3. Enter a **Name** for the mapping.
4. In the **Type** dropdown, select **Header Identity Mapping**.
5. Optional: In the **Attribute to Header Mapping** section, enter the name of the attribute to retrieve from the user web session in the **Attribute Name** field. For example, `sub`.
6. Enter the name of the HTTP requests header to contain the attribute value in the **Header Name** field. The HTTP header you specify here is the actual header name over the HTTP protocol, not an environment variable interpreted format. For example, enter the `User-Agent` browser type identifying header as `User-Agent`, not `HTTP_USER_AGENT`.
7. Select which attribute is used as the **Subject**.
8. Optional: In the **Certificate to Header Mapping** section, enter the header name included in a PEM-encoded client certificate. The row position correlates to the index in the client certificate chain. For example, the first row always maps to the leaf certificate. If you are using a certificate chain, click **Add Row** to add another row.
9. Click **Save**.

### Creating a JWT identity mapping

You can create a JWT Identity Mapping to make user attributes available in a signed JWT (JSON Web Token) sent to the application in a header.

#### About this task

The JWT issuer and signing configuration is defined in [Configuring Auth Token Management](#) on page 210.

When configuring identity mappings, the dot notation is supported so that session token structure can be maintained. For example, if the session token contains the following entry:

```
{
  "address": {
    "line1": "123 Any St",
    "line2": "Apt 123",
    "city": "Anytown",
    "state": "CO",
    "zip": "12345"
  }
}
```

You can define an identity mapping using the following entries to maintain the structure of the target JWT:

User Attribute Name	JWT Claim Name
---------------------	----------------

address.line1	address.line1
address.line2	address.line2
address.city	address.city
address.state	address.state
address.zip	address.zip

**Tip:** PingAccess engines provide a JWKS (JSON Web Key Set) endpoint at `/pa/authtoken/JWKS` that can be used by backend sites to validate the signature of the JWT.

### Steps

1. Navigate to **Access > Identity Mappings**.
2. Click **+ Add Identity Mapping**.
3. Enter a **Name** for the mapping.
4. In the **Type** dropdown, select **JWT Identity Mapping**.
5. Enter the name of the header to use when sending the signed JWT to the target application in the **Header Name** field. The HTTP header you specify here is the actual header name over the HTTP protocol, not an environment variable interpreted format. For example, enter the `User-Agent` browser type identifying header as `User-Agent`, not `HTTP_USER_AGENT`.
6. Enter the audience to be set as the `aud` claim in the signed JWT in the **Audience** field.
7. In the Attributes section, select a list type. An inclusion list includes only the specified attributes, and an exclusion list includes all attributes not specified.
8. If you selected an inclusion list, configure the inclusion list:
  - a) Enter the name of the attribute to retrieve from the user web session in the **User Attribute Name** field. For example, `sub`.
  - b) Enter the name of the JWT claim to contain the attribute value in the **JWT Claim Name** field.
  - c) Select which included attribute is used as the **Subject**.
9. If you selected an exclusion list, configure the exclusion list:
  - a) Enter the names of the attributes to exclude.
  - b) Select which included attribute is used as the **Subject**.
10. Optional: In the **Certificate to JWT Claim Mapping** field, enter the name of the JWT claim to contain the client certificate chain array.
11. **Client Certificate Chain Max Depth** If you are performing Certificate to JWT Claim Mapping, in the field, specify the maximum number of certificates from the client certificate chain included in the JWT claim array.
12. Optional: Click **Show Advanced** and select **Cache JWT** if you are performing **Certificate to JWT Claim Mapping**, in the . When enabled, a cached signed JWT will be used for repeated requests for a given user. If user attributes change or the key used to sign the JWT changes, a new JWT will be created even if JWT caching is enabled.
13. Click **Save**.

### Editing an identity mapping

You can edit the properties of an existing identity mapping.

### Steps

1. Navigate to **Access > Identity Mappings**.
2. Expand the identity mapping you want to edit.
3. Click .
4. Make the required changes.

5. Click **Save**.

### Deleting an identity mapping

You can delete an existing identity mapping.

#### Steps

1. Navigate to **Access > Identity Mappings**.
2. Expand the identity mapping you want to edit.
3. Click the Delete icon.
4. In the confirmation window that appears, click **Delete**.

### Virtual Hosts

Virtual Hosts enable PingAccess to protect multiple application domains and hosts.

A Virtual Host is defined by the host name and host port.

A wildcard (\*) can be used either to define either any host (\* : 443, for example) or any host within a domain (\*.example.com, for example). If a request matches more than one virtual host, the most specific match is used.

**Note:** Prior to availability of SNI in Java 8, an HTTPS port could only present a single certificate. In order to handle multiple Virtual Hosts you have to use a wildcard name certificate or the [Subject Alternative Name](#) (SAN) extension. With SNI available, Virtual Hosts can present different certificates on a single HTTPS port. You can assign which certificates (Key Pairs) are used by which Virtual Host on the [HTTPS Listeners](#) page.

The Agent Resource Cache TTL advanced field is used to control PingAccess Agent resources for each virtual host.

If you configure a trusted certificate group for a virtual host, or configure an engine key pair to associate it with a virtual host, those settings are used instead of any applicable HTTPS listeners or engine listeners for the virtual host.

### Creating a new virtual host

You can create a new virtual host.

#### Steps

1. Navigate to **Access > Virtual Hosts**.
2. Click **Add Virtual Host**.
3. Enter the **Host** name for the Virtual Host. For example: myHost.com. You can use a wildcard (\*) to indicate that any host name is acceptable. A wildcard host may also be specified (e.g. \*.example.com).
4. Enter the **Port** number for the Virtual Host. For example: 1234.
5. Enter the **Agent Resource Cache TTL** indicating the number of seconds the Agent can cache resources for this application. Only applies to destination of type *Agent*.
6. Click **Save**.

### Configuring virtual host trusted certificate groups

You can configure a virtual host trusted certificate group that can then be used to implement client certificate authentication.

#### About this task

Assigning a trusted certificate group to a virtual host provides a mechanism to authenticate using client certificates during any request to sites using the specified virtual host.

**Note:** Trusted certificate groups are applied at the host name level and are independent of the configured port. This means that a mapping to a virtual host of `*.example.com` will apply to requests received on virtual hosts `*.example.com:3000` and `*.example.com:443`.

### Steps

1. Navigate to **Access > Virtual Hosts**. Virtual Hosts that have certificate authentication configured will display the message *Client Certificate Authentication* in the associated bar.
2. Select and expand the Virtual Host you want to modify.
3. In the **Properties** list, click the  to select a **Trusted Certificate Group**.
4. Select the appropriate **Trusted Certificate Group**.
5. Click **Save**.
6. Add the following two *Groovy script rules* to force validation of the SNI and client certificate chain. [Apply these rules](#) to applications using this virtual host.

Validate SNI

```
if(exc?.getSslData()?.getSniServerNames()?.isEmpty())
{
    fail();
}
else
{
    pass();
}
```

Validate client certificate chain

```
if(exc?.getSslData()?.getClientCertificateChain()?.isEmpty())
{
    fail();
}
else
{
    pass();
}
```

### Editing a virtual host

You can edit the properties of an existing virtual host.

### Steps

1. Navigate to **Access > Virtual Hosts**.
2. Expand the virtual host you want to edit and click .
3. Make the required changes.
4. Click **Save**.

### Deleting a virtual host

You can delete an existing virtual host.

### Steps

1. Navigate to **Access > Virtual Hosts**.
2. Expand the virtual host you want to edit and click .
3. Click **Delete** to confirm.

## Web Sessions

Web sessions define the policy for web application session creation, lifetime, timeouts, and their scope.

You can configure any number of web sessions to scope the session to meet the needs of a target set of applications. This improves the security model of the session by preventing unrelated applications from impersonating the end user. Use the following tasks to configure secure Web Sessions for use with specific applications and to configure global Web Session settings.

### Application scoped Web Sessions

PingAccess Tokens can be configured to have their Web Sessions scoped to a specific application. This improves the security model of the session by preventing unrelated applications from impersonating the end user.

Several controls exist to scope the PA Token to an application:

<b>Audience Attribute</b>	The audience attribute defines who the token is applicable to and is represented as a short, unique identifier. Requests are rejected that contain a PA Token with an audience that differs from what is configured in the Web Session associated with the target Resource.
<b>Audience Suffix</b>	The audience attribute is also used as a suffix of the cookie name to ensure uniqueness. For example, PA.businessAppAudience.
<b>Cookie Domain</b>	The cookie domain can also optionally be set to limit where the PA Token is sent.

**Info:** In addition to these controls, parameters such as session timeout can be adjusted to match the policy requirements of each application.

Corresponding OAuth clients must be defined in PingFederate for each Web Session. Redirect URL whitelists defined in PingFederate dictate from which servers and domains the session can originate. Controlling this within PingFederate enables flexibility of the attribute contract (and its fulfillment) for that particular application. This ensures that each application and its associated policies only deal with attributes related to it.

### Configure Web Session Management settings

You can configure web session management sessions.

#### Steps

1. Navigate to **Access > Web Sessions**.
2. In the **Web Session Management** section, enter the **Key Roll Interval**, in hours, to specify how often you want to roll the keys (the default is 24 hours). Key rollover updates keys at regular intervals to ensure the security of signed and encrypted PA Tokens.
3. In the **Issuer** field, enter the published, unique identifier to be used with the Web session (the default is PingAccess). For example, set the issuer to a value that more closely represents your company. PingAccess inserts this value as the `iss` claim within the PA Token.
4. Select the **Signing Algorithm** used to protect the integrity of the PA Token (the default is `ECDSA using P-256 Curve`). PingAccess uses the algorithm when creating signed PA Tokens and when verifying signed tokens in a request from a user's browser. The algorithm is also used for signing tokens in Token Mediation use cases when PA Tokens are encrypted.
5. Select the **Encryption Algorithm** used to encrypt and protect the integrity of the PA Token (the default is `AES 128 with CBC and HMAC SHA 256`). PingAccess uses the algorithm when creating encrypted PA Tokens and when verifying them from a user's browser.

**Info:** Higher encryption levels are available if the administrative console supports it. To enable higher encryption levels, update the administrative console JRE to support unlimited strength security policy.

**Info:** In a clustered environment, be sure to add the security policy changes to the engines as well as the administrative console for the cluster.

6. Enter the browser **Cookie Name** that contains the PA Token (the default is `PA`).
7. In the **Session State Cookie Name** field, enter a name for the browser cookie to contain session state attributes.
8. In the **Update Token Window(s)** field, enter the number of seconds before the idle timeout is updated in the PA token. When this time window expires, PingAccess will reissue a new PA cookie.
9. In the **Nonce Cookie Time to Live (M)** field, enter the number of minutes for which the nonce cookie is valid. The default value is 5. PingAccess deletes cookies that are older than this threshold.
10. Click **Save**.

### Creating a Web Session

You can create a new web session.

#### Steps

1. Go to **Access > Web Sessions**
2. On the Web Session page, click **+ Add Web Session**.
3. Enter a unique **Name** for the web session, up to 64 characters, including special characters and spaces.
4. Select a **Cookie Type**.

An **Encrypted JWT** token uses authenticated encryption to simultaneously provide confidentiality, integrity, and authenticity of the PA Token.

A **Signed JWT** token uses asymmetric cryptography with a private/public key pairing to verify the signed message and to confirm that the message was not modified during transit.

**Encrypted JWT** is the default setting. Changing this setting may affect existing ongoing sessions, forcing the user to re-authenticate to access protected resources.

5. Specify the **Audience** that the PA Token is applicable to, represented as a short, unique identifier between 1 and 32 characters.

Requests are rejected that contain a PA Token with an audience that differs from what is configured in the Web Session associated with the target application. Changing this setting may affect existing ongoing sessions, forcing the user to re-authenticate to access protected resources.

6. Specify the **OpenID Connect Login Type** that defines how the user's identity is verified based on authentication performed by an OpenID Provider and how additional profile claims are obtained. Three login profiles are supported: **Code** and **POST**, and **x\_post**. Select a login profile.

#### Code

A standard OpenID Connect login flow that provides confidentiality for sensitive user claims. In this profile the relying party (PingAccess) makes multiple back-channel requests in order to exchange an authorization code for an ID Token and then exchange an access token for additional profile claims from the UserInfo endpoint at the provider (PingFederate). This login type is recommended for maximum security and standards interoperability.

#### POST

A login flow that uses the `form_post` response mode. This flow follows the [OAuth 2.0 Form Post Response Mode](#) draft specification. This option requires PingFederate 7.3 or later.

A form auto-POST response containing the ID Token (including profile claims) is sent to PingAccess from PingFederate via the browser after authentication. Back-channel communication between PingAccess and PingFederate is required for key management in order to validate ID Tokens. This

login type is recommended for maximum performance in cases where the exchanged claims do not contain information that should be hidden from the end user.

Be sure to select the **Implicit** grant type when configuring the OAuth Client within PingFederate (see [Configuring a Client](#)). The ID Token Signing Algorithm in PingFederate must be set to either one of the ECDSA algorithms or one of the RSA algorithms.

### **x\_post**

A login flow based on OpenID Connect that passes claims from the provider via the browser. As with the **POST** login type, select the **Implicit** grant type and use either one of the ECDSA algorithms or one of the RSA algorithms as the ID Token Signing Algorithm.

**Info:** If PingFederate 7.3 or later is used in the environment, we recommend using **POST** rather than **x\_post**, as **x\_post** was defined by Ping Identity prior to the development of the OAuth 2.0 Form Post Response Mode draft specification.

7. Specify the **Client ID** that was assigned when you created the OAuth Relying Party client within PingFederate (for more information, see [Configuring a Client](#) in the PingFederate documentation). Enter the unique identifier (Client ID).
8. Specify the **Client Secret** that was assigned when you created the OAuth Relying Party Client within PingFederate. Required when configuring the **Code** Login Type. Enter the secret (Client Secret).

**Info:** The OAuth Client you use with PingAccess Web sessions must have an OpenID Connect policy specified (for more information see [Configuring OpenID Connect Policies](#) in the PingFederate documentation).

9. Specify an **Idle Timeout** that defines the amount of time, in minutes, that the PA Token remains active, when no activity is detected by the user (the default is 60 minutes). Enter, in minutes, the length of time you want the PA Token to remain active when no activity is detected. Defining an idle expiration protects against unauthorized use of the resource by limiting the amount of time the session remains active when not being used. For example, idle expiration is useful when a user is no longer at the computer and does not log out of the session. When the idle expiration is reached, the session automatically terminates.

**Info:** If there is an existing valid PingFederate session for the user, an idle time out of the PingAccess session may result in its re-establishment without forcing the user to log in again.

10. Specify a **Max Timeout** that defines the maximum amount of time, in minutes, that the PA Token remains active (the default is 240 minutes). Enter, in minutes, the length of time you want the PA Token to remain active. Once the PA Token expires, an authenticated user must re-authenticate. This protects against unauthorized use of a resource, ensuring that a session ends after the specified time and requiring the user to re-authenticate to continue.

**Note:** This value needs to be set to a smaller value than the PingFederate Access Token Lifetime defined in the PingFederate Access Token Management instance. See [Configuring Reference-Token Management](#) in the *PingFederate Administrator's Manual* for more information.

11. To configure advanced settings, click **Show Advanced**.

12. Specify the valid **Cookie Domain** where the cookie is stored. For example, `corp.yourcompany.com`.

**Info:** If you set the Cookie Domain, all of your web resources must reside within that domain. If you do not set the Cookie Domain, the PA Token is recreated for each host domain where you access applications.

13. Select **Secure Cookie** to indicate that the PingAccess cookie must be sent using only HTTPS connections. Selected by default.

**Note:** Setting an invalid Cookie Domain or selecting **Secure Cookie** in a non-HTTPS environment causes authentication to fail. This results in PingAccess re-directing the user to re-authenticate with PingFederate indefinitely.

14. Select **HTTP-Only Cookie** to enable the `HttpOnly` flag on cookies that contain the PA Token. An `HttpOnly` flagged cookie is not accessible using non-HTTP methods such as calls via JavaScript

(for example, referencing `document.cookie`) and therefore cannot be easily stolen via cross-site scripting.

**15.**In the **SameSite Cookie** dropdown, select the level of restriction for when cookies may be sent in a cross-site request. The options are:

- Lax – The cookie should be sent on the initial navigation to a site, and is sent in same-site requests but not cross-site requests.
- None – The cookie is intended to be used across different sites without restriction.
- Disabled – The SameSite attribute is not set. This option is the default.

**Note:** See the [Known Issues and Limitations](#) for information about a browser issue that can prevent login if the SameSite Cookie attribute is set.

**16.**Configure the **Scopes** you want to request from the token provider when requesting the ID token. If you have a token provider configured, published scopes are available to select from the list based on the selected Client ID. You can specify unverified scopes by typing the scope and clicking **Use unverified scope "[scope]"**.

Your token provider must be properly configured to handle all of the requested scopes you specify, including any custom scope values.

**Note:** The user can access all attributes by examining browser traces. While they are integrity protected to prevent changes, any sensitive or confidential attributes can be viewed should the user decode the ID Token's value.

**17.**Select **Validate Session** so that PingAccess will validate sessions with the configured PingFederate instance during request processing. Use of this feature requires additional configuration in PingFederate. This option is not selected by default.

Session timeouts are synchronized between PingAccess and PingFederate when the following conditions are met:

- A minimum release of PingFederate 8.2 is deployed with **Authentication Session Settings** configured.
- You have selected the **Validate Session** checkbox.

Changing this setting may affect existing ongoing sessions, forcing the user to re-authenticate to access protected resources.

**18.**When **Refresh User Attributes** is enabled, PingAccess will periodically contact PingFederate to update user data used in evaluating policy claims. This option works in conjunction with the PingAccess Web Session Management features to automatically require user re-authentication if user attribute data used as issuance criteria for a token in PingFederate causes the token to be revoked.

For example, if the PingFederate OpenID Connect Policy has issuance criteria configured to only issue a token if the account is enabled, enabling this Web Session option allows PingAccess to terminate the session the next time the user accesses a protected resource if the user's account was disabled in the user datastore.

The **Refresh User Attributes Interval** determines the length of time the user data is cached, so the effect of a change that results in a session being terminated may take up to 60 seconds (by default) to take effect. This interval can be tuned by adding `pa.websession.refreshSessionInterval` to `conf/run.properties` and assigning it a value in seconds.

Changing this setting may affect existing ongoing sessions, forcing the user to re-authenticate to access protected resources.

This option is selected by default.

**19.**When **Cache User Attributes** is enabled, PingAccess caches user attributes internally for use in policy decisions. By doing this, an attribute list that is longer than the maximum cookie size can contain information used to evaluate access requests. In practice, this is 4096 bytes, although the maximum cookie size can vary depending on the browser.

When this option is disabled, user attribute data is encoded, signed or encrypted (depending on the web session cookie type), and stored in the browser's cookie store. The information is sent from the browser back to PingAccess with each request.

Changing this setting may affect existing ongoing sessions, forcing the user to re-authenticate to access protected resources.

This option is not selected by default.

20. Specify a **Consult Server Duration** to define the maximum amount of time, in seconds, that a PingAccess Agent caches policy decisions for the web session before sending a request to the Policy Server. This option only applies to agents.

**Info:** The value used for this setting should not be larger than the **Idle Timeout** value, and ideally, should be defined to be a value less than half the timeout.

21. Select **Request Preservation** to specify the type of request data to be preserved if the user is redirected to an authentication page when submitting information to a protected resource. Available options are **None**, **POST**, or **POST and Fragment**.

22. Specify the type of **Web Storage** to be used for request preservation data.

**Session Storage** is recommended. Use **Local Storage** if it is common for users to use Internet Explorer with security zones enabled and PingFederate is in a different zone than PingAccess.

23. Click **Save**.

### Editing a Web Session

You can edit the properties of an existing web session.

#### Steps

1. Navigate to **Access > Web Sessions**.
2. Expand the Web Session you want to edit and click .
3. Edit the Web Session.
4. Click **Save**.

### Deleting a Web Session

You can delete an existing web session.

#### About this task

**Info:** If the Web Session is currently associated with an application, you cannot delete it.

#### Steps

1. Navigate to **Access > Web Sessions**.
2. Expand the web session you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm the request.

### Unknown Resources

Unknown resources are those for which there is no associated application.

These settings define the error responses to be generated for requests that don't match the virtual host and context root of an application. Additionally, agents may be configured to allow unprotected access instead of returning an error response.

### Configuring unknown resource management

You can define the action to take when an unknown resource - a resource with no matching application - is requested.

## Steps

1. Navigate to **Access > Unknown Resources**.
2. Specify the **Error Status Code** for the HTTP response. This must be a client/server error code in the range 400 - 599.
3. Specify the name of the velocity **Error Template File** to use for generating the response body. This template file is located in the `PA_HOME/conf/template/` directory.
4. Specify the **Error Content Type** of the response; HTML, JSON, TEXT, or XML.
5. To audit unknown resource activity, select the **Audit** check box.
6. Specify the **Agent Default Mode** that determines whether an agent should **Deny** requests for unknown resources and generate an error response or allow requests to **Pass-Through** unfiltered. This default setting may be overridden by individual agents.
7. Specify the default agent resource **Cache TTL** (in seconds) to be used for unknown resources if **Pass-Through** mode is enabled.
8. Click **Save**.

## Networking

The **Networking** tab controls how PingAccess manages network requests and load balancing.

Choose from one of the following sections:

- [Availability Profiles](#) on page 220
- [HTTP Requests](#) on page 221
- [Listeners](#) on page 222
- [Load Balancing Strategies](#) on page 224
- [Proxies](#) on page 225

### Availability Profiles

Availability Profiles are used in a Site configuration to define how PingAccess classifies a backend target server as failed. Sites require the selection of an availability profile, even if only one target is provided.

A connection failure can be determined based on whether a backend target is not responding, or based on specified HTTP status codes that should be treated as failures of a specific backend target. For example, if a backend target is responding to requests with a "500 Server Error" status, it may be desirable to consider that server down even though the web service is responsive.

If multiple targets are specified in a site configuration but a load balancing strategy is not applied, the Availability Profile will cause the first listed target in the site configuration to be used unless it fails. Secondary targets will only be used if the first target is not available.

Currently, the only availability profile type is **On-Demand**. You may wish to create different profiles for different sites based on differing site needs for retry counts, retry delays, timeouts, or HTTP status codes.

### Creating an availability profile

You can create an availability profile to define when a backend server is considered failed.

## Steps

1. Go to **Networking > Availability Profiles**, then click **Add Availability Profile**.
2. Enter a unique descriptive name for the profile.
3. Select the **On-Demand** Type.
4. Enter the number of milliseconds to wait for a connection to be established to a backend target in the **Connect Timeout (ms)** field.
5. Enter the number in milliseconds the amount of time to wait before timing out the request for a pooled connection to the target site in the **Pooled Connection Timeout (ms)** field. Enter -1 for no timeout.

6. Enter the number in milliseconds the amount of time to wait before timing out the read of the response from a target site in the **Read Timeout (ms)** field. Enter -1 for no timeout.
7. Enter the number of times to retry a connection to a backend target before considering the target failed in the **Max Retries** field.
8. Enter the number of milliseconds to wait between retries in the **Retry Delay (ms)** field.
9. Enter the number of seconds to wait before trying a failed target again in the **Failed Retry Timeout (s)** field.
10. Optionally enter a list of HTTP status codes that should be considered as a failure in the **Failure HTTP Status Codes** field. The sequence for this list is not important.
11. Click **Save**.

### Editing an availability profile

You can edit the properties of an existing availability profile.

#### Steps

1. Navigate to **Networking > Availability Profiles**, expand the desired profile, then click .
2. Make the required changes to the profile.
3. Click **Save**.

### Deleting an availability profile

You can delete an existing availability profile.

#### Steps

1. Navigate to **Networking > Availability Profiles**.
2. Expand the desired profile, then click .
3. Click **Delete** to confirm.

### HTTP Requests

The settings for HTTP Requests are used to match a served resource with the originating client when one or more reverse proxies are between the client and the served resource.

For example, when a reverse proxy sits between the client and the PingAccess server or a PingAccess agent, the additional proxy might be identified as the client. Such proxies can be configured to inject additional headers to relay the originating client address.

The Host Source and Protocol Settings allow PingAccess to determine the effective URL of a request using a list of alternative headers. PingAccess uses this URL to apply security policies and perform HTTP redirects.

When the PingAccess Agent is behind a load balancer that is performing HTTPS offload, the load balancer must inject the Host Source and Protocol Source headers.

The **IP Source** section lets you specify an ordered list of header names to identify the source IP address. By default, `X-Forwarded-For` is configured as a heading.

The **Host Source** section lets you specify an ordered list of header names to identify the host source name. The Host Source options are only valid in proxy deployments. By default, `X-Forwarded-Host` and `Host` are configured as headings.

The **Protocol Source** section can be used to define the header that identifies the protocol used for the original request. The default value is `X-Forwarded-Proto`.

### Configuring an alternative IP Source header

You can configure an ordered list of header names to identify the source IP address.

### Steps

1. Navigate to **Networking > HTTP Requests**
2. In the **IP Source** section of the page, enter a header name to search for in the **Header Names** list.
3. If desired, click  to the right of an existing header to delete it from the list.
4. Select either *First* or *Last* for the **List Value Location** to determine whether, when a list of values is in the header, the first value or the last value in the list should be used as the IP Source value. The default value is *Last*.
5. Enable or Disable the **Fallback to Last Hop IP** checkbox to determine, if none of the listed headers is present in the request, whether the upstream IP address should be used for rule evaluation. If this value is disabled and no headers match, the network range rule will return a *Forbidden* status.

**Note:** This option uses the specified headers in an agent deployment, and uses networking layer information in a proxy deployment.

6. Click **Save**.

### Configuring an alternative host source header

You can configure an ordered list of header names to identify the host source name.

### About this task

**Note:** Host Source settings are valid for proxy deployments only.

### Steps

1. Navigate to **Networking > HTTP Requests**
2. In the **Host Source** section of the page, click **Header Names** to enter a header name to search for in the **Header Names** list.
3. If desired, click  to the right of an existing header to delete it from the list.
4. Select either *First* or *Last* for the **List Value Location** to determine, when a list of values is in the header, if the first value or the last value in the list should be used as the **Host Source** value. The default value is *Last*.
5. Click **Save**.

### Configuring an alternative protocol source header

You can configure a header name for a protocol source.

### Steps

1. Navigate to **Networking > HTTP Requests**.
2. In the **Protocol Source** section of the page, enter a header name in the **Header Name** field.
3. Click **Save**.

### Listeners

The Listeners configuration page is used to assign key pairs to the active HTTPS listeners, as well as to define additional listener ports for the PingAccess engine.

If you configure a trusted certificate group for a virtual host, or configure an engine key pair to associate it with a virtual host, those settings are used instead of any applicable HTTPS listeners or engine listeners for the virtual host.

### Cipher Suite ordering for HTTPS Listeners

PingAccess supports the use of a defined order for cipher suite usage to help ensure the most secure cipher suites are used first, regardless of the client request. The cipher suite order is defined in `<PA_HOME>/conf/run.properties` using the `tls.default.cipherSuites` property.

On new installs, or in the case of an upgrade to release 5.1 or later, this behavior is the default. You can disable this behavior and specify PingAccess to use the order provided by the client by setting `useServerCipherSuiteOrder` to `false` via the PingAccess API `/httpsListeners` endpoint.

### HTTPS Listeners

PingAccess listens for HTTPS requests on the ADMIN, ENGINE, and AGENT ports in all deployments, and on the CONFIG QUERY port in clustered deployments.

A key pair must be assigned to each listener. See [Key Pairs](#) for information on setting up a key pair. By default, the listeners are configured for HTTPS and use pre-generated key pairs associated with `localhost`.

**Table 3: HTTPS Listener Descriptions**

HTTPS Listener	Description
ADMIN	Listens for requests for the administrative user interface and the PingAccess REST APIs.
ENGINE	Listens for requests from PingAccess Agents.
AGENT	Listens for HTTP or HTTPS requests that are proxied to target web servers associated with <a href="#">Sites</a> .
CONFIG QUERY	Listens for requests for configuration information from replica administrative nodes and engine nodes in clustered deployments.

#### *Assigning a Key Pair to an HTTPS Listener*

You can assign a new key pair for any of the active HTTPS listeners.

#### Steps

1. Navigate to **Networking > Listeners**.
2. In the **HTTPS Listeners** section of the page, click the drop-down menu to the right of the listener and select a key pair.
3. Click **Save**.

#### Engine key pairs

##### *Assigning a Key Pair to a Virtual Host*

You can assign a key pair to a virtual host.

#### Steps

1. Navigate to **Networking > Listeners**
2. In the **Engine Key Pairs** section of the page, click **Edit** in the row the desired key pair appears in
3. Use the drop-down list to select select the virtual hosts for which the key pair should be used.
4. Click **Save**.

#### Engine listeners

##### *Defining an engine listener*

You can define a new engine listener.

#### Steps

1. Navigate to **Networking > Listeners**
2. Click **Add Engine Listener**.
3. Enter a descriptive name for the listener.

4. Enter the port the listener will open.

**Info:** Remember to open the port in the system firewall, or the listener will not be able to process any incoming requests.

5. If the port should listen for HTTP connections, clear the **Secure** option.

**Note:** By default, engine listeners listen for HTTPS connections to protect sensitive data.

6. Select a configured trusted certificate group to use for certificate authentication.

7. Click **Save**.

#### *Editing an engine listener*

You can modify the properties of an existing engine listener.

#### **Steps**

1. Navigate to **Networking > Listeners**
2. In the **Engine Listeners** section, expand an existing engine listener.
3. Click .
4. Make the required changes.
5. Click **Save**.

#### *Deleting an engine listener*

You can delete an existing engine listener.

#### **Steps**

1. Navigate to **Networking > Listeners**
2. In the **Engine Listeners** section, expand an existing engine listener.
3. Click .
4. Click **Delete** to confirm.

#### **Load Balancing Strategies**

Load Balancing Strategies are used in a Site configuration to distribute the load between multiple backend target servers. Load balancing settings are optional and only available if more than one target is listed for a site.

This functionality can replace a load balancer appliance between the PingAccess engine nodes and the target servers, allowing for a simpler network architecture.

The load balancing strategies currently available are `Header-Based` and `Round Robin`.

The `Header-Based` strategy requires a header be included in the request that defines the target to select from the **Site** configuration. This strategy has an option to fall back if the requested target is unavailable, or if the header is missing from the request.

The `Round Robin` strategy has a sticky session option that permits a browser session to be pinned to a persistent backend target. This strategy works in conjunction with the availability profile to select a target based on its availability, and the load balancer will not select a target that is in a failed state.

#### **Configuring a Load Balancing Strategy**

You can create a new load balancing strategy.

#### **Steps**

1. Go to **Networking > Load Balancing Strategies**
2. Click **Add Load Balancing Strategy**.
3. Enter a unique descriptive name for the strategy.
4. Select the **Type**, either `Header-Based` or `Round Robin`.

## 5. Configure the options for the selected Load Balancing Strategy type:

- For a `Header-Based` Load Balancing Strategy:
  - a. In the **Header Name** field, enter the name of the header that contains the selected target host.
  - b. If desired, click **Show Advanced** and select the **Fall Back to First Available Host** option to tell PingAccess to use the first available target defined for the site if the target specified in the header is not available or if the header is not present in the request.
 

**Note:** If this option is not enabled and the specified target is not available or the request header is not present, the client will receive a `Service Unavailable` response.
- For a `Round Robin` Load Balancing Strategy:
  - a. If browser sessions should not be pinned to a persistent backend target, clear the **Sticky Session Enabled** option. This option is enabled by default.
  - b. If the **Sticky Session Enabled** option is enabled, enter a cookie name to use in the **Cookie Name** field. This cookie is used by the PingAccess engine to track the persistent backend targets for a session.
 

**Note:** When a web session is defined, the **Cookie Name** field defines a cookie prefix to use. The rest of the cookie name comes from the **Audience** field in the Web Session.

### Editing a Load Balancing Strategy

You can edit the properties of an existing load balancing strategy.

#### Steps

1. Go to **Networking > Load Balancing Strategies**.
2. Expand the load balancing strategy you want to edit, then click .
3. Make any desired changes to the profile.
4. Click **Save**.

### Deleting a load balancing strategy

You can delete an existing load balancing strategy.

#### Steps

1. Go to **Networking > Load Balancing Strategies**.
2. Expand the load balancing strategy you want to edit, then click .
3. Click **Delete** to confirm.

### Proxies

This page contains the forward proxy configuration used when PingAccess makes requests to Sites or Token Providers.

#### Adding a proxy

You can add a forward proxy configuration to be used when PingAccess makes requests to sites or token providers.

#### Steps

1. Navigate to **Networking > Proxies**.
2. Click **Add Proxy**.
3. Specify a **Name** for the proxy configuration.
4. Enter an optional **Description**.
5. Enter the **Host** name for the forward proxy.
6. Enter the **Port** number for the forward proxy.
7. If the forward proxy requires authentication, select the **Requires Authentication** checkbox.

8. If required, enter the **Username** for the forward proxy.
9. If required, enter the **Password** for the forward proxy.
10. Click **Save**.

### Editing a proxy

You can edit the properties for an existing proxy.

### About this task

This task allows you to edit a proxy configuration.

**Note:** If you edit a proxy configuration that is associated with an engine or replica administrative node, you must download and install a new configuration on those nodes.

### Steps

1. Navigate to **Networking > Proxies**.
2. Expand an existing proxy configuration.
3. Click .
4. Make the required changes.
5. Click **Save**.

### Deleting a proxy

You can delete an existing proxy.

### Steps

1. Navigate to **Networking > Proxies**.
2. Expand an existing proxy configuration.
3. Click .
4. Click **Delete** to confirm.

## Security

The **Security** tab contains controls for certificates and key pairs.

Choose from one of the following sections:

- [Certificates](#) on page 226
- [Key Pairs](#) on page 228

### Certificates

You can import certificates into PingAccess to establish anchors used to define trust to certificates presented during secure HTTPS connections.

Outbound secure HTTPS connections such as communication with PingFederate for OAuth access token validation, identity mediation, and communication with a target Site require a certificate trusted by PingAccess. If one does not exist, communication is not allowed.

Certificates used by PingAccess may be issued by a CA or self-signed. CA-issued certificates are recommended to simplify trust establishment and minimize routine certificate management operations. Implementations of an X.509-based PKI (PKIX) typically have a set of root CAs that are trusted, and the root certificates are used to establish chains of trust to certificates presented by a client or a server during communication.

The following formats for X.509 certificates are supported:

- Base64 encoded DER (PEM)
- Binary encoded DER

A Certificate Group is a trusted set of anchor certificates used when authenticating outbound secure HTTPS connections. The Java Trust Store group contains all the certificates included in the keystore located in the Java installation at `$JAVA_HOME/lib/security/cacerts`. This group of certificates contains well-known, trusted CAs. If you are connecting to Sites that make use of certificates signed by a CA in the Java Trust Store, you do not need to create an additional Trusted Certificate Group for that CA. You cannot manage the Java Trust Store group from the PingAccess administrative console. Expand a section for steps to import and manage certificates and create and manage trusted certificate groups.

### Importing a certificate

You can import a new certificate.

#### Steps

1. Navigate to **Security > Certificates**.
2. Click **+** to the right of the **Certificates** subheading.
3. Enter an **Alias** for the certificate.
4. Click **Choose File** to select the certificate.
5. Click **Add** to import the certificate. A new certificate row appears on the Certificates page.

**Note:** If the Certificate is either expired or not yet valid, PingAccess displays a warning, but the import will proceed.

### Deleting a certificate

You can delete an existing certificate.

#### Steps

1. Navigate to **Security > Certificates**.
2. Expand the certificate you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm the deletion request.

**Info:** If the certificate is associated with a trusted certificate group, you cannot delete it.

### Creating a trusted certificate group

You can create a new trusted certificate group.

#### Steps

1. Navigate to **Security > Certificates**.
2. Click **+** to the right of the **Trusted Certificate Groups** heading.
3. Drag a certificate onto the box that appears.
4. Enter a **Name** for the group in the box that appears.
5. Select the **Use Java Trust Store** checkbox to set the new group to include the Java Trust Store group. For example, if you create your own intermediate CA certificate that is signed by a well-known CA in the Java Trust Store.
6. Select the **Skip certificate date checks** checkbox to allow PingAccess to ignore date-related errors for certificates that are not yet valid or have expired.
7. Click **Add**.
8. Additional certificates can be added to the new trusted certificate group by dragging them into the group.

### Adding a certificate to a trusted certificate group

You can add a certificate to an existing trusted certificate group.

### Steps

1. Navigate to **Security > Certificates**.
2. Drag a certificate into an existing trusted certificate group.

### Editing a trusted certificate group

You can edit the properties of an existing trusted certificate group.

### Steps

1. Navigate to **Security > Key Pairs**.
2. Expand the trusted certificate group you want to edit.
  - Add a certificate to the group by dragging it into the group from the certificate list.
  - Delete a certificate from the group by clicking - to the right of the certificate.
  - Edit the trusted certificate group parameters by clicking and then making your changes. If you edit these options, click **Save** to save them.

### Removing a certificate from a trusted certificate group

You can remove a certificate from a trusted certificate group.

### Steps

1. Expand the Trusted Certificate Group containing the certificate you want to remove.
2. Click on the certificate you want to remove.

### Deleting a trusted certificate group

You can delete an existing trusted certificate group.

### Steps

1. Navigate to **Security > Certificates**.
2. Expand the trusted certificate group you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm the deletion request.

### Key Pairs

PingAccess provides built-in Key Pairs, which are required for secure HTTPS communication.

A Key Pair includes a private key and an X.509 certificate. The certificate includes a public key and the metadata about the owner of the private key.

PingAccess listens for client requests on the administrative console port and on the PingAccess engine port. To enable these ports for HTTPS, the first time you start up PingAccess, it generates and assigns a Key Pair for each port. These generated Key Pairs are initially assigned on the **HTTPS Listeners** page.

Additionally, Key Pairs are used by the **Mutual TLS Site Authenticator** to authenticate PingAccess to a target Site. When initiating communication, PingAccess presents the client certificate from a Key Pair to the Site during the mutual TLS transaction. The Site must be able to trust this certificate in order for authentication to succeed.

**Info:** Ensure that the administrative console node and engines in a cluster have the same cryptographic configuration. For example, if you generate an elliptic curve Key Pair on the administrative console and the engines in the cluster are not configured to support elliptic curve Key Pairs, then the engines are not able to use that Key Pair for the engine **HTTPS Listeners** or as the Key Pair in a **Mutual TLS Site Authenticator**. Cryptographic configuration differences are often caused by having a Java Cryptographic Extension with limited strength providers installed (see the [Oracle Java documentation](#) for more information).

### Importing an existing key pair

You can import a key pair from a PKCS#12 file.

#### Steps

1. Navigate to **Security > Key Pairs**.
2. Click **Import**.
3. In the **Alias** field, enter a name that identifies the key pair. Special characters and spaces are allowed. This name identifies the key pair when assigning the key pair to various configurations such as [HTTPS Listeners](#).
4. Enter the **Password** used to protect the PKCS#12 file. PingAccess uses the password to read the file.
5. Click **Choose File** to locate the PKCS#12 file.
6. Click **Save** to import the file.

**Note:** If the key pair is either expired or not yet valid, PingAccess displays a warning, but the import will proceed.

### Generating a new key pair

You can generate a key pair and self-signed certificate.

#### Steps

1. Navigate to **Security > Key Pairs**.
2. Click **Add Key Pair**.
3. Enter the fields required for the new key pair.  
If the key pair is going to be used for incoming requests on multiple hosts or multiple IP addresses, enter additional **Subject Alternative Names** to meet those requirements.
4. Click **Save**.

### Generating a Certificate Signing Request

You can generate a certificate signing request (CSR) to establish more security and trust than using a self-signed certificate.

#### Steps

1. Go to **Security > Key Pairs**.
2. Click **Generate CSR** for the certificate you want to generate a CSR for. PingAccess generates a CSR file and your browser will download it.
3. Provide this file to a Certificate Authority (CA). The CA signs the file and provides a CSR Response that you can upload and use to replace the self-signed certificate. If the CA is well known, its certificates are installed by default in most browsers, and the user is not prompted to trust an unknown certificate.
4. When you receive the CSR response, follow the instructions at [Importing a Certificate Signing Request Response](#) on page 229.

### Importing a Certificate Signing Request Response

You can import a CSR response to replace the self-signed certificate in a key pair.

#### About this task

Click **CSR Response** and fill out the form.

**Note:** Before you import the CSR Response, import the signing CA certificate into PingAccess and add it to a [Trusted Certificate Group](#).

### Steps

1. Navigate to **Security > Key Pairs**.
2. Click **CSR Response** for the key pair the CSR applies to.
3. Select the **Trusted Certificate Group** to use for validating that the certificate in the CSR Response is correctly formed.
4. Choose the CSR Response file.
5. Click **Save**.

### Adding a certificate to a key pair

You can add a certificate to an existing key pair. You start with a leaf certificate, then add the intermediate and root certificates as required.

### About this task

**Note:** To modify the certificates included in a chain, remove the certificates from the key pair and add them again or delete the certificate and recreate it by importing a new certificate file and adding certificates to the key pair.

### Steps

1. Navigate to **Security > Key Pairs**.
2. Expand an existing key pair.
3. At the bottom of the key pair chain certificate list, click **Add Certificate**.
4. Click **Choose File** to browse for and select the certificate file.
5. Click **Add**.

### Removing a certificate from a key pair

You can remove a certificate from an existing key pair.

### About this task

**Note:** This procedure removes the last certificate in the chain. Certificates can only be removed in reverse order.

### Steps

1. Navigate to **Security > Key Pairs**.
2. Expand an existing key pair.
3. To remove the last certificate in the chain, click .
4. Click **Delete** to confirm.

### Downloading a Certificate

You can download a certificate when you need to configure a peer to trust a certificate used by PingAccess.

### About this task

For example, download the certificate for the key pair used by a **Mutual TLS Site Authenticator** and configure the target site to trust the certificate.

### Steps

1. Navigate to **Security > Key Pairs**.
2. Click **Download Certificate** in the row for the certificate you want to download.
3. Your browser will download the certificate and save it in your local filesystem.

## Deleting a key pair

You can delete an existing key pair.

### About this task

**Info:** If a key pair is currently in use, you cannot delete it.

### Steps

1. Navigate to **Security > Key Pairs**.
2. Expand the key pair you want to delete.
3. Click .
4. When prompted, click **Delete** to confirm the deletion request.

## System

The **System** tab contains controls for the administrative UI.

Choose from one of the following sections:

- [Admin Authentication](#) on page 231
- [Configuration Export/Import](#) on page 235
- [Clustering](#) on page 236
- [License](#) on page 240
- [Token Provider](#) on page 241
- [Token Validation](#) on page 249

### Admin Authentication

This page controls the PingAccess administrator authentication method. The default PingAccess administrator authentication method used to protect the administrative console is basic authentication (username and password).

You can use one of these authentication methods:

- Basic Authentication – Use a single set of credentials with the username `Administrator` and a password provided in the admin UI.
- Single Sign-On (SSO) – Use an OpenID Connect Token Provider to provide authentication.

For either authentication method, you can configure session properties such as the session cookie type and timeout values.

You can configure the authentication methods used for accessing the administrative APIs.

### Configuring basic authentication

You can configure basic authentication for the administrative user interface.

### About this task

The authentication default for the PingAccess administrative console is HTTP Basic Authentication. Basic Authentication uses the HTTP Authorization header to transmit the username and password credentials. The PingAccess server response contains a `PA_UI` cookie, which is a signed JSON Web Token. Subsequent HTTP requests send this cookie for authentication rather than the less secure HTTP Authorization header.

Basic Authentication supports one user – Administrator. This username cannot be changed. If you want to allow more than one user to access the admin UI, you should use SSO authentication.

### Steps

1. Go to **System > Admin Authentication > Basic Authentication**.

2. Click **Enable**.
3. Click **Save**.
4. Go to **System > Admin Authentication > Admin UI**.

**Note:** The current authentication setting is included in the menu title. For example, if basic authentication is configured as it is by default, the menu option is **Admin UI – Basic**.

5. In the **Authentication Method** section, select **Basic Authentication**.
6. Click **Save**.

### Changing the password for basic authentication

You can change the password used for basic authentication.

#### Steps

1. Go to **System > Admin Authentication > Basic Authentication**.
2. Enter the current administrator password.
3. Enter and confirm the new password.

**Important:** The new password must meet the configured password complexity rules defined in `pa.admin.user.password.regex` in `run.properties`.

4. Click **Save**.

### Configuring Admin UI SSO Authentication

You can configure single sign-on for the administrative user interface.

#### Before you begin

##### Prerequisites:

There are several configuration steps required within the OIDC token provider as well as PingAccess that you must complete to enable SSO. Expand a section to view those configurations. The Administrative SSO option can be configured to require a specific authentication mechanism, leveraging the OIDC token provider Requested AuthN Context Selector using the PingAccess [authentication requirements](#) options.

- The OIDC provider configuration must be completed. See the configuration instructions for your OIDC token provider:
  - [Configure PingFederate runtime](#)
  - [Configure PingOne](#)
  - [Configure OpenID connect](#)
- The OIDC token provider server certificate must be [imported](#) into a trusted certificate group, and that trusted certificate group must be associated with the OIDC token provider runtime.
- If you are using PingFederate, you must have a **profile** scope set up in PingFederate that includes the `openid`, `profile`, `address`, `email`, and `phone` scope values (see PingFederate documentation for [Configuring a Client](#)).

If you are using PingFederate as the OIDC token provider, when you configure the client in PingFederate, use the following options:

- The **Client Authentication** must be set to `None`
- The **Allowed Grant Types** must be set to `Implicit`
- The **Redirect URIs** must include `https://<PA_Admin_Host>:<PA_Admin_Port>/*`
- If you are not using administrative roles in PingAccess, the OpenID Connect **Policy** should be set to a policy that uses issuance criteria to restrict access based on some additional criteria.

**Warning:** If the selected OpenID Connect Policy does not use issuance criteria to limit which users can be granted an access token, *ALL* users in the associated identity store configured in PingFederate will be able to authenticate to the PingAccess Admin console and make changes. See [Identifying Issuance Criteria for Policy Mapping](#) in the *PingFederate Administrator's Manual*.

- If you are configuring administrative roles to enable the PingAccess auditor role, the issuance criteria defined in PingFederate should be defined to allow either an administrator or an auditor to be issued an access token. The attribute contract defined in the OpenID Connect Policy must include the additional attribute data that will be used to define the user's role in PingAccess.

### About this task

Use the Single Sign-On (SSO) Authentication page in PingAccess to enter the Client ID for the OAuth Client you created in the OIDC token provider.

**Info:** Complete the configuration for connecting to the PingFederate OAuth AS on the [Configuring PingFederate for PingAccess SSO](#) on page 246 page as well as completing the steps below.

### Steps

1. Go to **System > Admin Authentication > Admin UI**.

**Note:** The current authentication setting is included in the menu title. For example, if basic authentication is configured as it is by default, the menu option is **Admin UI – Basic**.

2. In the **Authentication Method** section, select **Single Sign-On**.

**Tip:** To define a fall back administrator authentication method if the OIDC token provider is unreachable, enable the `admin.auth=native` property in `run.properties`. This overrides any configured administrative authentication to [Basic Authentication](#).

3. In the **OpenID Connect Login Type** dropdown, select a login type:

- Code – The standard OIDC login flow. This option is the default.
- POST – A login flow using the `form_post` response mode, which returns response parameters as application/x-www-form-urlencoded HTML form values.
- x\_post – A login flow based on OIDC that passes claims from the provider via the browser using the implicit grant type.

4. In the **Client ID** field, enter the unique identifier assigned when you created the PingAccess OAuth client within your OIDC token provider.

5. In the **Client Secret** field, if you selected the Code login type or if you have enabled session validation, enter the secret assigned when you created the OAuth relying party client within your OIDC token provider.

6. Optional: If your environment requires an authentication requirements list, in the **Authentication Requirements** dropdown, select a defined authentication requirements list, or click **Create** to create a new list.

7. Optional: If you want to enable advanced settings, click **Show Advanced** and use one or more of the advanced options:

- a) Optional: To request one or more scopes from the OIDC token provider, select one or more scopes in the **Scopes** dropdown. If you have a token provider configured, published scopes are available to select from the list based on the selected Client ID. You can specify unverified scopes by typing the scope and clicking **Use unverified scope "[scopename]"**.

Your token provider must be properly configured to handle all of the requested scopes you specify, including any custom scope values.

**Note:** The user can access all attributes by examining browser traces. While they are integrity protected to prevent changes, any sensitive or confidential attributes can be viewed should the user decode the ID Token's value.

- b) Optional: To validate sessions with the configured PF instance during request processing, in the **Validate Session** options, click **Yes**. This option is not supported by PingOne or third-party OIDC token providers.
- c) Optional: To periodically refresh user data from the OIDC token provider, in the **Refresh User Attributes** options, click **Yes** and specify a **Refresh User Attributes Interval** in seconds.

- d) Optional: If you want PingAccess to cache user attribute information for use in policy decisions, click **Cache User Attributes**. When this option is disabled, user attribute information is encoded and stored in the session cookie.
- e) Optional: To enable the use of single logout, click **Use Single-Logout**. This option must be configured in the OIDC provider.

**Note:** If you are using PingFederate as a token provider, you should enable the **Check For Valid Authentication Session** in the PingFederate access token management configuration to prevent session replay.

- 8. Optional: If you want to enable role-based authorization, click **Enable Roles** and configure one or more roles:

- a) In the Administrator section, click **Add Required Attribute** once or more.

For a role to be granted, all configured attribute values must match.

- b) Enter an **Attribute Name** and **Attribute Value** for each required attribute.

**Note:** If you are using PingFederate as a token provider, the attribute name is defined in PingFederate under **OAuth Settings > OpenID Connect Policy Management > Your\_Policy > Attribute Contact** as an extension to the contract. The value to use depends on the configuration of the **Contract Fulfillment** tab for the policy.

The attribute named `group` in your attribute contract may be mapped to an LDAP server attribute source that contains a `groupMembership` attribute. A valid group membership for the administrator might be the group `cn=pingaccess-admins,o=myorg`. In this example, you would use `group` as the **Attribute Name** and `cn=pingaccess-admins,o=myorg` as the **Attribute Value**.

- c) Optional: If you want to add auditors, click **Add Required Attribute** in the Auditor section once or more.
- d) Optional: Enter an **Attribute Name** and **Attribute Value** for each required attribute.

- 9. Click **Save**.

### Configuring session properties

You can configure session properties for the administrative user interface.

#### Steps

- 1. Go to **System > Admin Authentication > Admin UI**.

**Note:** The current authentication setting is included in the menu title. For example, if basic authentication is configured as it is by default, the menu option is **Admin UI – Basic**.

- 2. Specify the **Cookie Type**, Encrypted JWT or Signed JWT.
- 3. Specify the unique **Audience** name the token is applicable to.
- 4. Specify an **Idle Timeout** in minutes. This sets the length of time you want the PA Token to remain active when no activity is detected. When the idle expiration is reached, the session automatically terminates.
- 5. Specify a **Max Timeout** in minutes. This sets the length of time you want the PA Token to remain active. Once the PA Token expires, an authenticated user must re-authenticate.
- 6. Specify an **Expiration Warning** in minutes. This specifies the point at which a user will be warned of upcoming session expiry.
- 7. Specify the **Session Poll Interval** in seconds. This sets the length of time between user info poll requests for the admin UI.
- 8. Click **Save**.

### Configuring API Authentication

You can configure authentication for the administrative API.

## About this task

**Info:** For more information on the PingAccess Administrative API, see [Administrative API Endpoints](#).

## Steps

1. Go to **System > Admin Authentication > Admin API OAuth**.

**Note:** The current API authentication setting is included in the menu title. For example, if Admin API OAuth is disabled, the menu option is **Admin API OAuth – Disabled**.

2. Select **Enable** to enable API OAuth authentication.
3. Enter the **Client ID** assigned when you created the OAuth client for validating OAuth access tokens (for more information about configuring a client ID in PingFederate, see [Configuring a Client](#)).
4. Enter the **Client Secret** assigned when you created the OAuth client in the OIDC token provider.
5. Select the **Scope** required to successfully access the API. For more information about defining scopes in PingFederate, see [Authorization Server Settings](#).
6. Enter the **Subject Attribute Name** you want to use from the OAuth access token as the subject for auditing purposes. At runtime, the attribute's value is used as the Subject field in audit log entries for the Admin API.
7. If you are using administrator/auditor roles, perform the following steps:
  - a) Select **Enable Roles** to enable role based authentication.
  - b) Click **Add Required Attribute** to define a new attribute that is required for Administrator access.

**Note:** More than one attribute may be defined here; if more than one is defined, all attribute values must match in order to grant access for the role.

- c) Enter the **Attribute Name** returned in the access token and the **Attribute Value** that defines the user as an administrator.

**Note:** The attribute name used here is defined in PingFederate under **OAuth Settings > OpenID Connect Policy Management > Your\_Policy > Attribute Contract** as an extension to the contract. The value to use depends on the configuration of the **Contract Fulfillment** tab for the policy.

The attribute named `group` in your attribute contract may be mapped to an LDAP server attribute source that contains a `groupMembership` attribute. A valid group membership for the administrator might be the group `cn=pingaccess-admins,o=myorg`. In this example, you would use `group` as the **Attribute Name** and `cn=pingaccess-admins,o=myorg` as the **Attribute Value**.

- d) If you want to define criteria for an auditor, select **Enable Auditor Role**.
  - e) Define criteria for the auditor in the same way you did for the administrator role.
  - f) Click **Add Required Attribute** to add an additional attribute.
8. Click **Save** to activate API Authentication.

## Configuration Export/Import

The Configuration Export/Import options create and restore a full PingAccess configuration.

You can back up and restore your configuration for disaster recovery or for testing purposes. You can restore your configuration on the same system or a new system, as long as the version used on the restore system matches the version used when the backup was made.

The configuration backup is stored as a `json` file, and contains the entire PingAccess configuration, with the exceptions of the administrative user configuration and the keys used for JWTs. It uses the same format as results from the Administrative APIs.

**CAUTION:** As the exported `json` file contains much of your PingAccess configuration, ensure the file is stored somewhere with appropriate security controls in place.

Sensitive data such as secrets and passwords are encrypted in the backup file. If you have [configured a master key encryptor](#) using the Addon SDK for Java, the host key file (JWK Set) is encrypted and included in the exported data.

You can modify the backup file directly. If you plan to do so, make an unmodified copy of the backup file before you begin.

### Exporting a PingAccess configuration

You can export your current configuration.

#### About this task

Large PingAccess configurations can take up to half an hour to export. During an export, the PingAccess configuration cannot be modified.

#### Steps

1. Navigate to **System > Configuration Export/Import**.
2. Click the **Download** button under **Export Configuration**. The downloaded file name is `pa-data-<timestamp>.json`.

**Note:** The *<timestamp>* value is formatted `MM-DD-YYYY.hh.mm.ss` - so a date and time of January 31, 2015 1:35 PM would be encoded as `01-31-2015.13.35.00` in the filename.

### Importing PingAccess configuration

You can import a previously saved configuration.

#### About this task

The **Import Configuration** option is a version-specific tool used to import a previously exported configuration. PingAccess checks the exported `json` file to ensure that the file came from the same version of PingAccess that it is being imported into.

Large PingAccess configurations can take up to a few hours to import. During an import, the PingAccess configuration cannot be modified or read.

#### To import a PingAccess configuration:

#### Steps

1. Navigate to **System > Configuration Export/Import**.
2. Under the **Import Configuration** heading, click **Choose File**.
3. Select the `json` export file containing the configuration to import.
4. Click **Import** to start the import process.
5. When prompted for confirmation, click **Confirm**.

**Important:** This operation is destructive, and overwrites your *entire* PingAccess configuration. Passwords in the system will revert to what they were when the backup was created. Unless you perform a backup prior to restoring a different configuration, the configuration prior to clicking **OK** will not be recoverable.

6. If the Agent or Admin listener key pairs change as a result of the import operation, restart PingAccess.
7. If the environment is clustered, ensure that the engines are using the proper engine keys. If they are not, re-save the engine to generate a new public key, and reconfigure the engine to use the newly generated key.

### Clustering

PingAccess can be configured in a clustered environment to provide higher scalability and availability for critical services.

While it is important to understand that there may be tradeoffs between availability and performance, PingAccess is designed to operate efficiently in a clustered environment.

PingAccess clusters are made up of three types of nodes:

<b>Administrative Console</b>	Provides the administrator with a configuration interface
<b>Replica Administrative Console</b>	Provides the administrator with the ability to recover a failed administrative console using a manual failover procedure.
<b>Clustered Engine</b>	Handles incoming client requests and evaluates policy decisions based on the configuration replicated from the administrative console

Any number of clustered engines can be configured in a cluster, but only one administrative console and one replica administrative console can be configured in a cluster.

Configuration information is replicated to all of the clustered engine nodes and the replica administrative node from the administrative console. State information replication is not part of a default cluster configuration, but some state information can be replicated using PingAccess subclusters.

### PingAccess Subclusters

Subclusters are a method to provide better scaling of very large PingAccess deployments by allowing multiple engine nodes in the configuration to share certain information. A load balancer is placed in front of each subcluster in order to distribute connections to the nodes in the subcluster.

Subclusters serve three purposes:

- Providing fault-tolerance for mediated tokens if a cluster node is taken offline.
- Reducing the number of STS transactions with PingFederate when the front-end load balancer does not provide a sticky session.
- Ensure rate limits are enforced properly if the front-end load balancer does not provide a sticky session.

If token mediation and rate limiting are not used in your environment, subclustering is not necessary.

**Info:** This cache can be tuned using the EHCACHE Configuration Properties listed in the **Configuration Properties** documentation.

PingAccess provides clustering features that allow a group of PingAccess servers to appear as a single system. When deployed appropriately, server clustering can facilitate high availability of critical services. Clustering can also increase performance and overall system throughput. It is important to understand, however, that availability and performance are often at opposite ends of the deployment spectrum. Thus, you may need to make some configuration tradeoffs that balance availability with performance to accommodate specific deployment goals.

In a cluster, you can configure each PingAccess engine, or node, as an administrative console, a replica administrative console, or a runtime engine in the `run.properties` file. Runtime engines service client requests, while the console server administers policy and configuration for the entire cluster (via the administrative console). The replica administrative console provides a backup copy of the information on the administrative node in the event of a non-recoverable failure of the administrative console node. A cluster may contain one or more runtime nodes, but only one console node and only one replica console node. Server-specific configuration data is stored in the PingAccess administrative console server in the `run.properties` file. Information needed to bootstrap an engine is stored in the **bootstrap.properties** file on each engine.

At startup, a PingAccess engine node in a cluster checks its local configuration and then makes a call to the administrative console to check for changes. How often each engine in a cluster checks the console for changes is configurable in the engine `run.properties` file.

Configuration information is replicated to all engine nodes. By default, engines do not share runtime state. For increased performance, you can configure engines to share runtime state by configuring cluster interprocess communication using the `run.properties` file.

**Info:** Runtime state clustering consists solely of a shared cache of security tokens acquired from the PingFederate STS for **Token Mediation** use cases using the **Token Mediator Site Authenticator**.

Engine nodes include a status indicator that indicates the health of the node and a **Last Updated** field that indicates the date and time of the last update. The status indicator can be green (good status), yellow (degraded status), or red (failed status).

The status is determined by using the value for `admin.polling.delay` as an interval to measure health:

<b>Green (good status):</b>	The replica administrative node contacted the primary administrative node on the last pull request.
<b>Yellow (degraded status):</b>	The replica administrative node contacted the primary administrative node between 2 and 10 intervals.
<b>Red (failed status):</b>	The replica administrative node has either never contacted the primary administrative node, or it has been more than 10 intervals since the nodes communicated.

## Engines

### *Configuring an engine node*

You can configure an engine node as part of a cluster.

### About this task

For each engine:

### Steps

1. Click **System > Clustering**
2. Click **+ Add Engine** to configure a new engine.
3. Enter a **Name** for the engine. Special characters and spaces are allowed.
4. Enter a **Description** of the engine.
5. If applicable, specify an **HTTP Proxy** for the engine. Click **Create** to create an HTTP proxy.
6. If applicable, specify an **HTTPS Proxy** for the engine. Click **Create** to create an HTTPS proxy.
7. Specify the **Engine Trusted Certificate** to use for cases where a TLS-terminating network appliance, such as a load balancer, is placed between the engines and the admin node.
8. Click **Save & Download** to generate and download a public and private key pair into the `<enginename>_data.zip` file for the engine. This file is prepended with the name you give the engine. Depending on your browser configuration, you may be prompted to save the file.
9. Copy the zip file to the `PA_HOME` directory of the corresponding engine in the cluster and unzip it. The engine uses these files to authenticate and communicate with the administrative console.

**Info:** Generate a new key for an engine at any time by clicking **Save & Download** and unzipping the `<enginename>_data.zip`

10. On Linux systems running the PingAccess engine, change the permissions on the extracted archive on the engine to replace the files with a new set of configuration files. When that engine starts up and begins using the new files, PingAccess deletes the old `key.pa.jwk` to mode 400 by executing the command `chmod 400 conf/pa.jwk` after extracting the zip file.

11. Start each engine.

**Info:** For information on configuring engine to share information with each other in a cluster, see [Configure a PingAccess Cluster](#).

### *Editing an engine node*

You can edit the name and description of an engine node within your cluster, and download a new public key if necessary.

#### **Steps**

1. Go to **System > Clustering**.
2. Expand the node you want to edit, then click .
3. Edit the node **Name** or **Description**, as appropriate.
4. If a new public key is needed, click **Save & Download**.
5. If a new public key is not needed, click **Save**.

### *Removing an engine node*

You can remove an engine node from the cluster.

#### **Steps**

1. Go to **System > Clustering**.
2. Expand the engine node you want to delete and click to permanently remove all references to the node from the cluster.
3. Click **Delete** in the confirmation window.

#### **Administrative nodes**

##### *Configuring the administrative node*

You can configure one PingAccess node as the administrative node.

#### **About this task**

This procedure allows you to specify an HTTP or HTTPS proxy. If proxy configuration is defined in a properties file (`bootstrap.properties` or `run.properties`), it will take precedence over UI or API configuration.

If a proxy is configured on a replica administrative node, when failing over and before removing the `bootstrap.properties` file, the administrative node should have the same proxy configuration.

**Warning:** If you are promoting a replica administrative node to an administrative node, remove the `bootstrap.properties` file from the replica administrative node.

#### **Steps**

1. Go to **System > Clustering > Administrative Nodes**.
2. Enter the host and port for the administrative console. The default is `localhost:9000`.
3. If applicable, specify an **HTTP Proxy** for the engine. Click **Create** to create an HTTP proxy.
4. If applicable, specify an **HTTPS Proxy** for the engine. Click **Create** to create an HTTPS proxy.
5. Click **Save**.

##### *Configuring the replica administrative node*

You can configure one PingAccess node as a replica administrative node to provide an alternative if the administrative node fails.

#### **About this task**

When using a replica administrative node, you must define a key pair to use for the CONFIG QUERY listener that includes both the administrative node and the replica administrative node. You can do this either by using a wildcard certificate or by defining subject alternative names in the key pair that

include the replica administrative node's DNS name. If you use a replica administrative node in your configuration, configure the replica administrative node before defining the engine nodes, or the `bootstrap.properties` files generated for the engine nodes will not include information about the replica administrative node.

In addition to the configuration below, the Replica Administrative node includes a status indicator that indicates the health of the node and a read-only **Last Updated** field that indicates the date and time of the last update. The status indicator can be green (good status), yellow (degraded status), or red (failed status).

The status is determined by using the value for `admin.polling.delay` as an interval to measure health:

<b>Green (good status):</b>	The replica administrative node contacted the primary administrative node on the last pull request.
<b>Yellow (degraded status):</b>	The replica administrative node contacted the primary administrative node between 2 and 10 intervals.
<b>Red (failed status):</b>	The replica administrative node has either never contacted the primary administrative node, or it has been more than 10 intervals since the nodes communicated.

**Note:** If you are configuring a replica administrative node in the environment, that must be done before you configure the engines.

## Steps

1. Go to **System > Clustering > Administrative Nodes**.
2. Configure the **Host** value. This name and port pair must match either a subject alternative name in the key pair or be considered a match for the wildcard specified if the key pair uses a wildcard in the common name.
3. If applicable, specify an **HTTP Proxy** for the engine. Click **Create** to create an HTTP proxy.
4. If applicable, specify an **HTTPS Proxy** for the engine. Click **Create** to create an HTTPS proxy.
5. Specify the **Replica Administrative Node Trusted Certificate** to use for cases where a TLS-terminating network appliance, such as a load balancer, is placed between the engines and the admin node.
6. Click **Save & Download** to download the `<replicaname>_data.zip` file for the replica administrative node. PingAccess automatically generates and downloads a public and private key pair into the `bootstrap.properties` file for the node. The **Public Key** is indicated on this screen.
7. Copy the downloaded file to the replica administrative node's `PA_HOME` directory and unzip it.
8. If the replica administrative node is running on a Linux host, execute the command `chmod 400 conf/pa.jwk`.
9. Edit `PA_HOME/conf/run.properties` on the replica administrative node and change the `pa.operational.mode` value to `CLUSTERED_CONSOLE_REPLICA`.
10. Start the replica administrative node.
11. Verify replication has completed by monitoring the `PA_HOME/log/pingaccess.log` file and looking for the message "Configuration successfully synchronized with administrative node".

## License

This page lets you view the details of your PingAccess license or upload a new license.

The **System > License** page displays the details of the current license.

You can upload a new license file using this page. The new license is compared to the existing license, and unusual discrepancies such as the new license having a sooner expiration date than the existing

license are flagged. After reviewing any warnings, you can choose to import the new license file, replacing the existing file.

In a clustered environment, the license file on the administrative node is replicated to all of the engine nodes and the replica administrative node. The engine nodes do not require a license to function, but some default templates appear differently depending on the information in the license.

When a license is about to expire or has expired, the UI displays a warning, and a WARNING-level message is added to the PingAccess Console log.

**Note:** If the installation has a running configuration, and the admin shuts down the server, removes the license file from the filesystem, and restarts the server, the existing runtime configuration will continue to work. However, the admin will have to install a new license file on the filesystem, or upload one via the UI, to enable accessing and applying changes via the UI.

### Uploading a PingAccess license

You can upload a new PingAccess license file.

#### About this task

When you select a new license file to import, PingAccess compares the new license file's attributes with those of the current license before installing it. The UI displays a warning ribbon on the page in certain cases. For example, if the expiration date of the uploaded license is sooner than the current license, the UI will flag that as a warning.

If the new license is acceptable, you can commit it, and the new license will replace the old.

#### Steps

1. Navigate to **System > License** to view the attributes of the installed license.
2. Scroll down to the **Import License** section.
3. Click **Choose a File** to select a license file.

**Warning:** The UI will display a warning ribbon for the following cases:

- **Expiration date:** The new license is set to expire on a date earlier than that of your current license.
- **Expired:** The new license is already expired.
- **License version:** The major version of the license doesn't match the current version of PingAccess.
- **Max Applications:** The new license is limited to support fewer applications than your current license.

4. Click **Import** to import the selected license.

**Note:** If you selected the wrong license, you can either click **Remove** to remove the selected license from the **Import License** section of the page, or you can click **Choose File** to select a different license file.

5. Click **Confirm** to install the selected license.

#### Token Provider

You can configure the token provider for PingAccess. The supported token providers are PingFederate, PingOne, and common providers using the OpenID Connect protocol.

#### PingFederate

- [Configuring PingFederate runtime](#) on page 242
- [Configuring PingFederate administration](#) on page 244
- [Configuring the OAuth Resource Server](#) on page 245

- [Configuring PingFederate for PingAccess SSO](#) on page 246

### PingOne

- [Configuring PingOne](#) on page 247

### Common Token Provider

- [Configuring OpenID Connect](#) on page 247
- [Configuring OAuth Authorization Server](#) on page 249

### PingFederate

#### Configuring PingFederate runtime

You can configure a secure connection to the PingFederate runtime.

### Before you begin

Before configuring a secure connection to the PingFederate runtime, it is necessary to export the PingFederate certificate and import it into a trusted certificate group in PingAccess. Perform the following steps:

1. In PingFederate, export the certificate active for the Runtime Server. See [SSL Server Certificates](#) in the *PingFederate Administrator's Manual* for more information.
2. Import the certificate into PingAccess.
3. Create a Trusted Certificate Group if one does not already exist.
4. Add the certificate to a Trusted Certificate Group.

### About this task

**Info:** For information on setting PingFederate up as an OAuth Authorization Server, see [Enabling the OAuth AS](#) and [Authorization Server Settings](#) in the PingFederate documentation.

Once the PingFederate Runtime connection is saved, PingAccess will test the connection to PingFederate. If the connection cannot be made, a warning will be displayed in the admin interface, and the PingFederate runtime is prevented from saving.

The steps displayed depend on your environment. In a new deployment, some of the PingFederate configuration information is imported automatically from the PingFederate well-known endpoint. If you have upgraded from PingAccess 5.2 or earlier and have an existing token provider configuration, this information is provided manually. If you have performed an upgrade and want to see the new version of this page, configure the token provider using the `/pingfederate/runtime` API endpoint. For more information, see [Administrative API Endpoints](#).

**Note:** Configuring PingFederate as a token provider using the `/pingfederate/runtime` overwrites the existing PingFederate configuration.

Once you have successfully configured the token provider, click **View Metadata** to display the metadata provided by the token provider. To update the metadata, click **View Metadata > Refresh Metadata**.

### Configure the connection to the PingFederate Runtime

#### Steps

1. Go to **System > Token Provider**.
2. Click **PingFederate**.
3. Click the **Runtime** tab.
4. In the **Issuer** field, enter the PingFederate issuer name.
5. Optional: Enter a **Description** for the PingFederate instance.
6. From the **Trusted Certificate Group** list, select the certificate group the PingFederate certificate is in. This list is available only if you select **Secure**.

7. To configure advanced settings, click **Show Advanced**.
8. If hostname verification for secure connections is not required for either the runtime or the back channel servers, select the **Skip Hostname Verification** check box.
9. Optional: To use a configured proxy for back channel requests, select the **Use Proxy** check box.  
**Note:** If the node is not configured with a proxy, requests are made directly to PingFederate.
10. Optional: Select **Use Single-Logout** to enable single logout. To use this feature, SLO must be configured on the OIDC provider.
11. Optional: Enter the **STS Token Exchange Endpoint** to be used for token mediation if it is different from the default value of `<issuer>/pf/sts.wst`.
12. Click **Save**.

**Info:** After you save this configuration and [Configuring the OAuth Resource Server](#) on page 245, a PingFederate Access Validator is available for selection when you define OAuth-type rules in Policy Manager.

#### Configure PingFederate runtime (original workflow)

If your PingAccess deployment has been upgraded from version 5.2 or earlier with an existing token provider configuration, and you have not configured a token provider using the `/pingfederate/runtime` API endpoint, this workflow is displayed for configuring a PingFederate runtime.

#### Before you begin

Before configuring a secure connection to the PingFederate runtime, it is necessary to export the PingFederate certificate and import it into a trusted certificate group in PingAccess. Perform the following steps:

1. In PingFederate, export the certificate active for the Runtime Server. See [SSL Server Certificates](#) in the *PingFederate Administrator's Manual* for more information.
2. Import the certificate into PingAccess.
3. Create a Trusted Certificate Group if one does not already exist.
4. Add the certificate to a Trusted Certificate Group.

#### About this task

**Info:** For information on setting PingFederate up as an OAuth Authorization Server, see [Enabling the OAuth AS](#) and [Authorization Server Settings](#) in the PingFederate documentation.

Once the PingFederate Runtime connection is saved, PingAccess will test the connection to PingFederate. If the connection cannot be made, a warning will be displayed in the admin interface, and the PingFederate runtime is prevented from saving.

Once you have configured the token provider, click **View Metadata** to display the metadata provided by the token provider. To update the metadata, click **View Metadata > Refresh Metadata**.

#### Steps

1. Go to **System > Token Provider**.
2. Click the **PingFederate** radio option.
3. Click the **Runtime** tab.
4. In the **Host** field, enter the PingFederate runtime host name or IP address for the PingFederate Runtime.
5. In the **Port** field, enter the PingFederate runtime port number.
6. Optional: In the Base Path field, enter the base path, if needed, for the PingFederate runtime. It must start with a slash - for example: `/federation`.

7. Click the **Audit Level** check box to log information about the transaction to the audit store. PingAccess audit logs record a selected subset of transaction log information at runtime and are located in the `/logs` directory of your PingAccess installation.
  8. Select the **Secure** check box if PingFederate is expecting HTTPS connections.
  9. From the **Trusted Certificate Group** list, select the certificate group the PingFederate certificate is in. This field is available only if you select **Secure** in the previous step.
  10. To configure advanced settings, click **Show Advanced**.
  11. Click **Add Back Channel Server**.
  12. Enter one or more `hostname:port` pairs in the **Back Channel Servers** list.
  13. If the back channel uses HTTPS, enable the **Back Channel Secure** option. This option becomes available when at least one back channel server is defined.
  14. If the back channel uses an alternate base path, enter the path in the **Back Channel Base Path** field.
  15. If hostname verification for secure connections is not required for either the Runtime or the Back Channel Servers, enable the **Skip Hostname Verification** option.
  16. If hostname verification is required, enter the host name PingAccess should expect in the **Expected Hostname** field.
  17. To use a configured proxy for back channel requests, select the **Use Proxy** check box.
- Note:** If the node is not configured with a proxy, requests are made directly to PingFederate.
18. Select **Use Single-Logout** to enable single logout. To use this feature, SLO must be configured on the OIDC provider.
  19. Click **Save**.

**Info:** After you save this configuration and [Configuring the OAuth Resource Server](#) on page 245, a PingFederate Access Validator is available for selection when you define OAuth-type rules in Policy Manager.

#### *Configuring PingFederate administration*

You can configure your PingFederate administration settings.

#### **About this task**

For information on the PingFederate Administration API see [PingFederate Administrative API](#) in the PingFederate documentation.

Once the PingFederate Administration configuration is saved, PingAccess will test the connection to PingFederate. If the connection cannot be made, an error will be displayed in the admin interface, and the configuration will not be saved.

#### **Steps**

1. Navigate to **System > Token Provider > Administration**.
2. Enter the **Host** name or IP address for access to the PingFederate Administrative API.
3. Enter the **Port** number for access to the PingFederate Administrative API.
4. Optional: Enter the **Base Path** for the PingFederate Administrative API.

The **Base Path** must start with a slash (/).

For example: `/path`

5. Enter the **Admin Username**.  
This username only requires Auditor (read only) permissions in PingFederate.
6. Enter the **Admin Password**.
7. Select **Audit Level** to log information about the transaction to the audit store. PingAccess audit logs record a selected subset of transaction log information at runtime and are located in the `/logs` directory of your PingAccess installation.

8. Enable **Secure** if PingFederate is expecting HTTPS connections.
9. From the **Trusted Certificate Group** list, select the group of certificates to use when authenticating to PingFederate. PingAccess requires that the certificate in use by PingFederate anchor to a certificate in the associated Trusted Certificate Group. This field is available only if you enable **Secure**.
10. To configure advanced settings, click **Show Advanced**.
11. To use a configured proxy for API requests, select the **Use Proxy** checkbox.

**Note:** If the node is not configured with a proxy, requests are made directly to PingFederate.

12. Click **Save**.

**Tip:** To view OIDC metadata provided by the token provider, click **View Metadata** after saving the token provider configuration.

#### *Configuring the OAuth Resource Server*

When receiving OAuth-protected API calls, PingAccess acts as an OAuth Resource Server, checking with the PingFederate OAuth Authorization Server on the validity of the bearer access token it receives from a client. In order to validate the token, a valid OAuth client must exist within the PingFederate OAuth Authorization Server.

#### **Before you begin**

Prior to configuring this option, PingFederate Administration Configuration must be completed.

#### **About this task**

**Note:** This configuration is optional and needed only if you plan to validate PingFederate OAuth access tokens.

#### **Steps**

1. Navigate to **System > Token Provider > OAuth Resource Server**
2. Enter the OAuth **Client ID** you defined when creating the PingAccess OAuth client in PingFederate.
 

**Info:** When you configure an OAuth client in PingFederate, be sure to select [Access Token Validation](#) as the allowed grant type. For more information, see [Configuring a Client](#) in the *PingFederate Administrator's Manual*.
3. Enter the **Client Secret** you defined when creating the PingAccess OAuth client within PingFederate.
4. Select **Cache Tokens** to retain token details for subsequent requests. This option reduces the communication between PingAccess and PingFederate.
5. If **Cache Tokens** is enabled, specify the **Token Time To Live** by entering the number of seconds to cache the access token. The default value of -1 means no limit. This value can be -1 or above and must be less than the PingFederate Token Lifetime.
6. In the **Subject Attribute Name** field, enter the attribute you want to use from the OAuth access token as the subject for auditing purposes. For example, `username`. At runtime, the attribute's value is used as the Subject field in audit log entries for API Resources with policies that validate access tokens. The attribute must align with an attribute in the [OAuth access token attribute contract](#) defined within PingFederate.
7. If multiple Access Token Managers are configured in PingFederate, select the **Send Audience** option to send the URI the user requested as the `aud` OAuth parameter to select an Access Token Manager.
 

**Note:** Use of this option requires that the Access Token Management instances be configured with appropriate Resource URIs. Matching of the Resource URI is performed on a most-specific match basis.
8. To enable the use of OAuth 2.0 token introspection select the **Use Token Introspection Endpoint** option.

**Note:** This option is only supported with PingFederate 8.2 or later.

9. Click **Save** to save your changes.

### Configuring PingFederate for PingAccess SSO

You can configure PingFederate to enable administrator SSO for PingAccess.

#### About this task

To enable administrator SSO to PingAccess, configure the following settings within the PingFederate AS. Click the icon (  ) next to each section heading to access additional configuration information. For example, click  next to **Roles and Protocols** to open a new window and view the Choosing Roles and Protocols page of the PingFederate documentation.

**Note:** The information below is an example configuration and does not cover all required steps for each PingFederate OAuth Settings page discussed, only fields necessary for successful SSO to the PingAccess administrative console. Fields not mentioned are not necessary for this configuration (see [Using OAuth Menu Selections](#) for configuration details of the PingFederate OAuth Settings pages).

**Note:** You must complete the configuration for connecting to the PingFederate OAuth AS instance you plan to use (see [Configuring PingFederate administration](#) on page 244).

#### Roles and Protocols

- Enable the OAuth 2.0 AS role and the OpenID Connect protocol.
- Enable the IdP Provider role and a protocol.

#### Password Credential Validator (PCV)

- Create a PCV for authenticating administrative users.

#### Adapters

- Create an HTML Form IdP Adapter and specify the PCV you configured.

#### Authorization Server Settings

- Select **Implicit** in the Reuse Existing Persistent Access Grants for Grant Types section.

#### Access Token Management

- Select **Internally Managed Reference Tokens** as the Access Token Management Type.
- Extend the contract by adding the Username attribute on the Access Token Attribute Contract page.

#### OpenID Connect Policy Management

**Info:** We recommend creating an OpenID Connect Policy to use specifically for PingAccess administrative console authentication.

- Delete all of the attributes that appear in the Extend the Contract section of the Attribute Contract page. The only required attribute is **sub**.
- Select **Access Token** as the Source and **Username** as the Value on the Contract Fulfillment page.

#### Client Management

**Info:** We recommend creating a Client to use specifically for PingAccess administrative console authentication.

- Select **None** for Client Authentication.
- Add the location of the PingAccess host as a Redirect URI. For example: `https://localhost:9000/*`
- Select **Implicit** as an Allowed Grant Type.

- Select one of the elliptic curve (**ECDSA**) algorithms as the OpenID Connect ID Token Signing Algorithm and select the OpenID Connect Policy to use for PingAccess administrative console authentication.

### IdP Adapter Mapping

- Map the HTML Form IdP Adapter Username value to the USER\_KEY and the USER\_NAME contract attributes for the persistent grant and the user's display name on the authorization page, respectively.

### Access Token Mapping

- Map values into the token attribute contract by selecting **Persistent Grant** as the Source and **USER\_KEY** as the value for the Username attribute. These are the attributes included or referenced in the access token.

## PingOne

### *Configuring PingOne*

You can configure PingOne as the token provider.

### Before you begin

You must have the PingOne issuer ID, or have access to the PingOne console, to perform this procedure.

### About this task

Once you have successfully configured the token provider, click **View Metadata** to display the metadata provided by the token provider. To update the metadata, click **View Metadata > Refresh Metadata**.

### Steps

1. Go to **System > Token Provider**.
2. Select **PingOne**.
3. In the **Issuer** field, enter the PingOne issuer ID. This information is available in the PingOne console.
4. Optional: Enter a description for the connection.
5. In the **Trusted Certificate Group** list, select a trusted certificate group that PingAccess will use when authenticating to PingOne.
6. To configure the connection to use a configured proxy, click **Show Advanced** and select **Use Proxy**.
7. Click **Save**.

### Common

#### *Configuring OpenID Connect*

You can configure OpenID Connect token provider settings.

### About this task

Once you have successfully configured the token provider, click **View Metadata** to display the metadata provided by the token provider. To update the metadata, click **View Metadata > Refresh Metadata**.

### Steps

1. Go to **System > Token Provider**.
2. Click **Change Token Provider Type**.
3. When prompted to confirm the change, click **Confirm**.
4. Select **OpenID Connect**.
5. In the **Issuer** field, enter the OpenID Connect provider's issuer identifier.
6. In the **Description** field, enter a description for the token provider.
7. Select the **Audit Level** check box to record requests to OpenID Connect provider to the audit store.

8. From the **Trusted Certificate Group** list, select the group of certificates to use when authenticating to OpenID Connect provider. PingAccess requires that the certificate in use by OpenID Connect provider anchor to a certificate in the associated Trusted Certificate Group.
9. If required, click **Add Query Parameter** and enter custom query parameter name and value pairs used by the OpenID Connect provider.
10. To configure advanced settings, click **Show Advanced**.
11. To use a configured proxy, select the **Use Proxy** check box.
 

**Note:** If the node is not configured with a proxy, requests are made directly to the token provider.
12. Select **Use Single-Logout** to enable single logout. To use this feature, SLO must be configured on the OIDC provider.
13. Click **Save**.

#### Configure token provider specific options

You can configure plugins that perform particular functions for the selected token provider type.

In the case of the PingAccess for Azure AD solution, the plugin addresses the following problems:

- **Transform data** - The format of data returned from the OIDC UserInfo endpoint results in some unexpected JSON formatting. This data is transformed into a format that PingAccess can easily digest.
- **Use the Azure AD Graph API** - If the groups attribute contains more than 200 groups, the `id_token` contains a level of indirection that points to a URL in the Azure AD Graph API. Through the creation of a simple purpose-driven application, you can communicate with the Azure ID Graph API to retrieve the complete list of groups.
- **Retrieve group display names** - The groups attribute is a list of GUIDs. The groups for a user are only provided as GUIDs since User-friendly names for AAD groups are not globally unique. Configure the Graph API call to include the group names along with the GUID for creation of more robust policies.

1. First, [Create the Azure AD Graph API application](#)
2. Next, [Configure token provider specific options](#)

#### Prerequisite: Create the Azure AD Graph API application

To use the Azure AD Graph API, an application must exist whose purpose is to provide an **Application ID** and **Key** that PingAccess will use as the **Client ID** and **Client Secret** for communication with the Graph API. Create the application in Azure AD via the **App Registrations** blade using the following criteria:

- **Name** - Enter a unique name for the application, for example: *Graph API app*
  - **Application Type** - Web app / API
  - **Sign-on URL** - This field is not relevant for this particular use case, but is required by Azure AD. Enter the PingAccess host.
1. When the application has been created, navigate to the application in the list.
  2. Select **Required permissions** and click **Add**.
  3. Choose the **Windows Azure Active Directory** API, select the following permission, and click **Save**.
    - Application Permissions - Read directory data
  4. Copy the **Application ID**.
  5. Generate and copy a **Key**.

#### Configure token provider specific options

1. Navigate to **System > Token Provider**. Scroll to the **Token Provider Specific Options** section.
2. From the **Type** list, select **Azure Active Directory**.
3. Select the **Use Azure AD Graph API** checkbox.
4. In the **Client ID** field, enter the **Application ID** you copied from the Azure AD API application you created.
5. In the **Client Secret** field, paste the **Key** you copied.

## 6. Select **Retrieve Group Display Names**.

**Important:** To retrieve groups data for a particular application in the token, the manifest for that application must be modified to include a Group Membership Claim. In the **App Registrations** blade, select the application and click the **Manifest** button. Locate the "groupMembershipClaims" entry and specify a group type, for example "SecurityGroup".

## 7. Click **Save**.

### *Configuring OAuth Authorization Server*

You can configure the OAuth Authorization Server.

### **Steps**

1. Navigate to **System > Token Provider**.
2. Select **OAuth Authorization Server**.
3. In the **Description** field, enter a description for the authorization server.
4. In the **Targets** field, enter one or more `hostname:port` pairs for the OAuth Authorization Server. Click **Add Target** to add additional targets.
5. In the **Introspection Endpoints** field, specify the OAuth endpoint through which the token introspection operation is accomplished.
6. Optional: Select the **Audit Level** checkbox to record requests to OAuth Authorization server to the audit store.
7. Select the **Secure** checkbox if OAuth Authorization server is expecting HTTPS connections. When selected, use the **Trusted Certificate Group** list to select the group of certificates to use when authenticating to OAuth Authorization Server. PingAccess requires that the certificate in use by OAuth Authorization Server anchor to a certificate in the associated Trusted Certificate Group.
8. In the **Client ID** field, enter the unique identifier assigned when you created the PingAccess OAuth client within your OAuth Authorization Server.
9. In the **Client Secret** field, enter the Client Secret associated with the Client ID.
10. Optional: Select the **Cache Tokens** to retain token details for subsequent requests. This option reduces the communication between PingAccess and OAuth Authorization Server. When selected, use the **Token Time To Live** checkbox to enter the number of seconds to cache the access token. A value of -1 means there is no limit. This value should be less than the OAuth Authorization Server Token Lifetime.
11. In the **Subject Attribute Name** field, enter the attribute you want to use from the OAuth access token as the subject for auditing purposes. At runtime, the attribute's value is used as the Subject field in audit log entries for API Resources with policies that validate access tokens.
12. Select the **Send Audience** checkbox to send the URI the user requested as the `aud` OAuth parameter for PingAccess to the OAuth 2.0 Authorization Server.
13. To configure advanced settings, click **Show Advanced**.
14. To use a configured proxy, select the **Use Proxy** checkbox.
15. Click **Save**.

**Note:** If the node is not configured with a proxy, requests are made directly to the token provider.

### **Token Validation**

API and Web + API applications can be configured to use access token validators to locally verify signed and/or encrypted access tokens. This feature works in conjunction with token providers that support JWS and/or JWE validation.

**Tip:** When using PingFederate as the token provider for this feature, export the `Generated: ENGINE` keypair located at **Security > Key Pairs** from PingAccess and import to PingFederate Trusted CAs.

### **Adding an access token validator**

You can add an access token validator to verify signed or encrypted access tokens.

### Steps

1. Go to **System > Token Validation**.
2. Click **Add Access Token Validator**.
3. Specify a **Name** for the token validator.
4. In the **Type** list, select the type of key you want to validate. The type of key is specified in token provider configuration.

**Note:** For information related to PingFederate configuration, see [Configure JSON token management](#) for information about the configuration of PingFederate.

5. Enter a **Description** for the token validator.
6. In the **Path** field, specify the endpoint path used to verify the signature. This entry must start with a slash (/), and must not end with a slash (/). Host and port are derived from PingFederate token provider configuration. A query string is permitted in the path.
7. In the **Subject Attribute Name** field, enter the attribute expected as the subject. If the specified SAN is not present in the token, validation will fail. This is a required field.
8. In the **Issuer** field, enter the expected value of the issuer that is to be included in the access token. If configured, and the value is not present in the token, validation will fail.
9. In the **Audience** field, specify the audience value that is to be included in the access token. If configured, and the value is not present in the token, validation will fail.
10. Click **Save**.

### Editing an access token validator

You can edit an existing access token validator.

### Steps

1. Go to **System > Token Validation**.
2. Expand the application on the **Properties** tab and click .
3. Make the required changes.
4. Click **Save**.

### Deleting an access token validator

You can delete an existing access token validator.

### Steps

1. Go to **System > Token Validation**.
2. Expand the access token validator you want to delete and click .
3. Click **Delete** to confirm.

### Configure OAuth key management

You can configure settings for OAuth key management.

### Steps

1. Go to **System > Token Validation**.
2. Select the **Key Roll Enabled** checkbox to enable key rolling. Deselect to disable key rolling.
3. Specify the interval at which you want to roll keys by entering a value, in hours, in the **Key Roll Enabled** field.
4. Click **Save**.

# Agents and Integrations

---

## PingAccess for AWS

---

### PingFederate Environment Requirements for PingAccess for AWS

#### Introduction

In addition to deploying a demonstration environment that includes a basic PingFederate instance, you can configure the PingAccess for AWS solution to deploy with support for an existing PingFederate environment. You may choose this installation method for test or production deployments with a PingFederate environment that is external to your AWS VPC.

This document is a guide for administrators that describes the components the automation process is expecting to be configured in your PingFederate environment, how to configure those components, and how to include information about your environment to the automation.

While variations to these PingFederate requirements do exist, and while it is possible to deviate from these instructions in some cases, this document is intended to describe a minimum configuration and, as such, these instructions would be outside the scope of this document at this time.

At a minimum, your PingFederate environment requires the following components:

1. [Install the AWS Password Credential Validator](#)
2. [Configure the AWS PCV instance](#)
3. [Configure a Simple Password Credential Validator Instance](#)
4. [Create an IdP adapter](#)
5. [Add a Persistent Grant Extended Attribute](#)
6. [Configure default scope values](#)
7. [Configure an Access Token Manager instance](#)
8. [Configure an AWS PCV Resource Owner Credentials Mapping](#)
9. [Configure an IdP adapter mapping](#)
10. [Configure an IdP Adapter Access Token mapping](#)
11. [Configure an AWS PCV Access Token mapping](#)
12. [Create an OpenID Connect policy](#)
13. [Configure the PingAccess Admin SSO OAuth client](#)
14. [Configure the Resource Owner API Client OAuth client](#)
15. [Create and \(optionally\) export a PingFederate certificate](#)

#### Create an IAM User in AWS

This document describes the steps required to create an IAM User that will be used by the AWS Password Credential Validator.

**Note:** If your PingFederate instance resides in Amazon EC2, do not use these steps. The preferred method is instead to create an IAM Role and assign the proper permissions:

1. Navigate to **Services > IAM**.
2. Click **Roles**.
3. Click **Create role**.
4. Select **AWS service > EC2** and specify the **EC2** use case.
5. Click **Next: Permissions**.
6. Filter for **IAMReadOnlyAccess** and select this item.
7. Click **Next: Review**.

8. Provide a **Role name** and optional **Role description**.
9. Click **Create role**.
10. Assign this role to your PingFederate EC2 instance by right clicking the EC2 instance and choosing **Instance Settings > Attach/Replace IAM Role**.

1. In AWS, navigate to **Services > Security, Identity & Compliance > IAM**.

2. Click **Users**.

3. Click **Add User**.

4. Specify a **User name**. For example: `awspcv_api`

5. For **Access** type, select **Programmatic access**.

6. Click **Next**.

7. Select **Attach existing policies directly**.

8. Filter the list for **IAMReadOnlyAccess** and select this item.

9. Click **Next**.

10. Click **Create User**.

11. Copy the **Access key ID** for use with the AWS PCV instance that you will create in PingFederate.

12. In the **Secret access key** field, click **Show**.

13. Copy the **Secret access key** for use with the AWS PCV you will create.

**Important:** You must copy the Secret access key at this stage. The key will be masked permanently when you navigate away from this page.

14. Click **Close**.

### PingFederate configuration requirements

The following sections describe the PingFederate configuration elements expected by the automation. At a minimum, your PingFederate environment should include these components.

#### Install the AWS Password Credential Validator

The following steps describe how to install the AWS password credential validator (PCV).

1. Obtain the PCV file, `aws-password-credential-validator-<version>.jar`.
2. Copy the file to your PingFederate installation at `%PingFedHome%/pingfederate/server/default/deploy`.
3. Restart PingFederate.

#### Configure the AWS PCV instance

The following steps describe how to configure the AWS PCV instance.

1. In PingFederate, navigate to **Server Configuration > Password Credential Validators**.
2. Click **Create New Instance**.
3. Specify the **Instance Name**: `AWS PCV`
4. Specify the **Instance ID**: `AwsPcv`
5. Select the **Instance Type**: `AWS Username Password Credential Validator`
6. Click **Next**.
7. Enter the **Access Key** and **Secret Key** for the *IAM user* you created.

**Note:** If your PingFederate instance is in EC2, and you have *created an IAM Role*, leave these fields blank.

**Note:** If your PingFederate instance is located in the same VPC, you can leave these fields blank.

8. Click **Next**.

9. Click **Done**.

10. Click **Save**.

## Configure a Simple Password Credential Validator Instance

The following steps describe how to configure the Simple PCV instance. This PCV will be assigned to an IdP adapter instance.

**Note:** You can use an existing PCV/Adapter configuration for Admin SSO if it meets these configuration requirements.

1. In PingFederate, navigate to **Server Configuration > Password Credential Validators**.
2. Click **Create New Instance**.
3. Specify the **Instance Name**: SimplePcv
4. Specify the **Instance ID**: SimplePcv
5. Select the **Instance Type**: Simple Username Password Credential Validator
6. Click **Next**.
7. Click **Add a new row to 'Users'**.
8. Specify a **Username** and **Password** to use for PingAccess Admin SSO, confirm the password, and click **Update**. For example: joe/2Federate.
9. Click **Next**.
10. Click **Done**.
11. Click **Save**.

## Create an IdP adapter instance

The following steps describe how to create an IdP adapter instance.

1. Navigate to **IdP Configuration > Adapters**.
2. Click **Create New Instance**.
3. Specify the **Instance Name**: HtmlFormIdpAdapter
4. Specify the **Instance ID**: HtmlFormIdpAdapter
5. Select the **Instance Type**: HTML Form IdP Adapter
6. Click **Next**.
7. Click **Add a new row to 'Credential Validators'**.
8. Select the **SimplePcv** PCV you created and click **Update**.
9. Click **Next** (x2).
10. On the **Adapter Attributes** screen, select the **Pseudonym** checkbox.
11. Click **Next** (x2).
12. Click **Done**.
13. Click **Save**.

## Add a Persistent Grant Extended Attribute

The following steps describe how to add a Persistent Grant Extended Attribute.

1. Navigate to **OAuth Settings > Authorization Server Settings**.
2. In the **Persistent Grant Extended Attributes** section, type **ACTIONS** and click **Add**.
3. Scroll to the bottom and click **Save**.

## Configure default scope values

The following steps describe how to add values to the default scope.

1. Navigate to **OAuth Settings > Scope Management**.
2. Specify a **Default Scope Description**: `Default Permissions`
3. Enter the following **Scope Value** and **Scope Description** items and click **Add** with each:

Scope Value	Scope Description
-------------	-------------------

address	Address access
email	Email access
offline_access	Offline access
openid	OpenID Connect login
phone	Phone Number access
profile	Profile access

4. Click **Save**.

### Configure an Access Token Manager instance

The following steps describe how to create an Access Token Manager instance.

1. Navigate to **OAuth Settings > Access Token Management**.
2. Click **Create New Instance**.
3. Enter the **Instance Name**: Internally Managed Reference Tokens
4. Enter the **Instance ID**: default
5. Select the **Instance Type**: Internally Managed Reference Tokens
6. Click **Next** (x3).
7. On the **Access Token Attribute Contract** screen, extend the contract by adding attributes **Actions** and **Username**, clicking **Add** after each.
8. Click **Next** (x3).
9. Click **Done**.
10. Click **Save**.

### Configure an AWS PCV Resource Owner Credentials Mapping

The following steps describe how to create an AWS PCV Resource Owner Credentials Mapping.

1. Navigate to **OAuth Settings > Resource Owner Credentials Mapping**.
2. Select the AWS PCV from the **Source Password Validator Instance** list and click **Add Mapping**.
3. Click **Next**.
4. On the Contract Fulfillment screen, select the Source and Value for each Contract item as follows:

Contract	Source	Value
ACTIONS	Password Credential Validator	actions
USER_KEY	Password Credential Validator	rolename

5. Click **Next** (x2).
6. Click **Done**.
7. Click **Save**.

### Configure an IdP adapter mapping

The following steps describe how to configure an IdP adapter mapping.

1. Navigate to **OAuth Settings > IdP Adapter Mapping**.
2. In the **Source Adapter Instance** list, select the **HtmlFormIdpAdapter** you created.
3. Click **Add Mapping**.
4. Click **Next**.
5. On the **Contract Fulfillment** screen, configure entries as follows:

Contract	Source	Value
----------	--------	-------

ACTIONS	Text	sso
USER_KEY	Adapter	username
USER_NAME	Adapter	username

6. Click **Next** (x2).
7. Click **Save**.

### Configure an IdP Adapter Access Token mapping

The following steps describe how to configure an IdP Adapter Access Token mapping.

1. Navigate to **OAuth Settings > Access Token Mapping**.
2. Select the **IdP Adapter: HtmlFormAdapter** from the **Context** list, **Internally Managed Reference Tokens** from the **Access Token Manager** list, and click **Add Mapping**.
3. On the **Contract Fulfillment** screen, configure entries as follows:

Contract	Source	Value
Actions	Persistent Grant	ACTIONS
Username	Persistent Grant	USER_KEY

4. Click **Next** (x2).
5. Click **Save**.

### Configure an AWS PCV Access Token mapping

The following steps describe how to configure an AWS PCV Access Token mapping.

1. Navigate to **OAuth Settings > Access Token Mapping**.
2. Select the **Validator: AWS PCV** from the **Context** list, **Internally Managed Reference Tokens** from the **Access Token Manager** list, and click **Add Mapping**.
3. On the **Contract Fulfillment** screen, configure entries as follows:

Contract	Source	Value
Actions	Persistent Grant	ACTIONS
Username	Persistent Grant	USER_KEY

4. Click **Next** (x2).
5. Click **Save**.

### Create an OpenID Connect policy

The following steps describe how to create an OpenID Connect policy.

1. Navigate to **OAuth Settings > OpenID Connect Policy Management**.
2. Click **Add Policy**.
3. Enter the **Policy ID: PA-WAM**
4. Enter the **Policy Name: PA-WAM**
5. Select the **Access Token Manager: Internally Managed Reference Tokens**
6. Click **Next**.
7. Delete all items beneath **Extend the Contract**.
8. Click **Next** (x2).
9. For the **Attribute Contract** sub, select a **Source** of **Access Token**, and a **Value** of **Username**.
10. Click **Next** (x2).
11. Click **Done**.
12. Click **Set as Default**.

13. Click **Save**.

### Configure the PingAccess Admin SSO OAuth client

The following steps describe how to create the PingAccess Admin SSO OAuth client that is used by the automation.

1. Navigate to **OAuth Settings > Clients** and click **Create New**.
2. Enter the **Client ID**: pa\_sso
3. Enter the **Name**: PingAccess Admin SSO
4. For **Client Authentication**, select **None**.
5. Enter the following **Redirect URIs** and click **Add** after each:
  - https://\*:9000
  - https://\*:9000/\*
6. Select the following **Allowed Grant Types**:
  - Authorization Code
  - Refresh Token
  - Implicit
7. Click **Save**.

### Configure the Resource Owner API Client OAuth client

The following steps describe how to create the Resource Owner API Client OAuth client that is used by the automation.

1. Navigate to **OAuth Settings > Clients** and click **Create New**.
2. Enter the **Client ID**: api\_ro
3. Enter the **Name**: Resource Owner API Client
4. For **Client Authentication**, select **Client Secret** and specify a Secret of 2Access.
5. Select the following **Allowed Grant Types**:
  - Resource Owner Password Credentials
  - Access Token Validation (Client is a Resource Server)
6. Click **Save**.

### Create and (optionally) export a PingFederate certificate

Your PingFederate installation must use a valid certificate that contains the PingFederate hostname as either the Common Name or Subject Alternative Name. You can import a valid certificate into PingFederate or you can create a certificate using PingFederate.

The following steps describe how to use PingFederate to create and export a certificate for use with the automation.

1. Navigate to **Server Configuration > SSL Server Certificates**.
2. Click **Create New**.
3. Enter a **Common Name** that matches the URL for the PingFederate server. For example, if your PingFederate server is hosted at `mypingfed.myserver.com:9031`, the Common Name will be `mypingfed.myserver.com`.
4. Enter appropriate values for **Organization** and **Country**.
5. Click **Next**.
6. Choose to make the certificate active for both the runtime server and the admin console.
7. Click **Done**.
8. On the **Certificate Management** screen, locate the certificate you created and click **Export**.
9. Select **Certificate Only** and click **Next**.

10. On the **Export & Summary** screen, click **Export** to download the certificate.

11. Click **Done**.

12. Locate the certificate file and open in a text editor.

13. Copy and save the certificate data between the first and last lines. Do not copy the first and last lines that identify the certificate file. You will add this data to the [api.json file](#) used by the automation.

### Modify api.json to include details about your environment

Users who wish to deploy the PingAccess for AWS solution with an existing PingFederate instance must edit the `api.json` file that is included with the automation package and supply this file to the automation. You will provide details about your PingFederate environment that will be used to configure the PingAccess token provider and Admin Authentication components.

The following instructions assume that you have followed and meet the [PingFederate configuration requirements](#) on page 252.

**Important:** It is important to note that if your AWS deployment fails for any reason while you are using a modified `api.json` file, you will need to replace the file in the S3 repository with the modified file. This is due to changes that are made to the file by the automation, such as the obfuscation of password data.

The `api.json` file is located in the automation package at `<automation package>/s3-bucket-root/pingaccess/conf`.

If you meet the PingFederate configuration requirements, the following changes will need to be made to the `api.json` file:

- `"pingFederate": "host"` : - Enter the hostname for your PingFederate server. Do not include ports or prefixes.
- `"pingFederate": "trustedCertificateGroupName"` : - Enter "Trust Any".
- `"pingFederateAdmin": "host"` : - Enter the hostname for your PingFederate server. Do not include ports or prefixes.
- `"pingFederateAdmin": "trustedCertificateGroupName"` : - Enter "Trust Any" for testing or debugging purposes, otherwise [Add a PingFederate Certificate object to the automation](#). Using a PingFederate certificate object overrides this property.

If your PingFederate server is running on non-default ports, enter the appropriate ports in this file.

### (Optional) Add a PingFederate Certificate object to the automation

You can use an [existing PingFederate certificate](#) with the automation by adding the following top level object to `api.json`:

```
"pingFederateCertificate": {
  "alias": "PingFederate",
  "fileData": "<certificate_data>"
}
```

Replace `<certificate_data>` with the data you copied and saved in [Create and \(optionally\) export a PingFederate certificate](#) on page 256.

### Add the api.json file to the automation

After you have made the appropriate changes to the `api.json` file, upload the file to your S3 bucket at `<S3 bucket>/pingaccess/conf`.

## Solution Setup Guide for PingAccess for AWS

### Introduction

This document provides the steps required to perform a variety of tasks related to setting up and configuring the PingAccess for AWS solution. You can choose to deploy this solution in a demonstration environment that includes a basic PingFederate instance or you can choose to deploy with an [existing PingFederate instance](#).

Review the [prerequisites](#) prior to setting up this solution.

After you have deployed the solution, you can [configure an application](#).

### Setup and deployment

In this section, you will perform the tasks required to setup and deploy the PingAccess for AWS solution. Along with PingAccess, this solution includes the optional deployment and configuration of a basic PingFederate instance.

When setup is complete, you will be able to configure a protected application using PingFederate as the token provider.

To setup and deploy the solution, you will:

1. Review the setup [AWS prerequisites](#) on page 258
2. [Obtain the automation ZIP file](#) on page 260
3. [Create the PingAccess software repository](#) on page 260
4. [Populate the S3 bucket](#) on page 261
5. [Create the PingAccess key pair](#) on page 261
6. [Create the PingAccess VPC](#) on page 262
7. [Configure Security Groups](#) on page 267
8. [Access the PingAccess administration console](#) on page 268
9. [Access the PingFederate administration console](#) on page 268

### AWS prerequisites

Prior to beginning the setup of this solution, you must first satisfy some prerequisites. These prerequisites will ensure that you have details and resources that are required for use in the setup phase. You may have one or more of these items available as part of an existing deployment. Create the items you require.

Prerequisites include the following items:

1. [Create an Amazon Web Services account](#) on page 258
2. [Choose your region](#) on page 258
3. [Choose your AMIs](#)
4. [Register domain name with Route53](#)
5. [Create a certificate](#)

### Create an Amazon Web Services account

To make use of this solution, you need an [Amazon Web Services](#) account. Create an account if necessary.

**Important:** While many of the components required for this solution are [Free Tier](#) eligible, following the steps in this document may lead to incurred costs.

### Choose your region

Specify the region in which your AWS environment should reside.

**Note:** For release 1.0, if your region does not support Signature Version 2, [modify templates to support Signature Version 4](#). This action is not required for release 1.0.1 and up.

## Choose your AMIs

Throughout the setup process, you will be asked to specify the ID of the Amazon Machine Image (AMI) that you want to use. AMIs are region-specific, so you will require an AMI that is available to your region.

**Note:** For release 1.0, if your region does not support Signature Version 2, [modify templates to support Signature Version 4](#). This action is not required for release 1.0.1 and up.

**Important:** AMIs available from AWS have default configurations that may not meet the security requirements of some network environments. Administrators are encouraged to assess the default configurations of the AMIs and make necessary modifications to satisfy the security requirements of their environment as needed.

At this time, you may only use the AMI types specified in this document. Your configuration may include the use of only a single Amazon Linux AMI ID for all required AMI IDs, but you may choose a combination where possible using the following supported types:

**Note:** **Amazon Linux 2** has not been tested with this solution, and is unsupported at this time. When choosing an Amazon Linux AMI, select the **Amazon Linux AMI**.

- **Bastion host AMI ID:** Amazon Linux
- **Admin AMI ID:** Amazon Linux or RHEL 7.4
- **Engine AMI ID:** Amazon Linux or RHEL 7.4
- **PingFederate AMI ID:** Amazon Linux
- **Internal CA AMI ID:** Amazon Linux

The EC2 instance type is specified by the templates you will use. For optimal performance, use the instance type specified.

To find the ID of the AMI you want to use:

1. In AWS, navigate to **Services > Compute > EC2**.
2. On the EC2 Dashboard, click **Launch Instance**. This page displays the AMIs available in your selected region.
3. Make note of the AMIs you want to use, along with their AMI ID. In the following example, the AMI ID is **ami-9fa343e7**:

**Red Hat Enterprise Linux 7.4 (HVM), SSD Volume Type - ami-9fa343e7**

**Note:** In release 1.0, if you are customizing the AMIs used by the setup templates, you must modify `/pingaccess/templates/security/internal-ca.yaml` and `/pingaccess/templates/security/pingfederate-setup.yaml` to specify the AMI ID you want to use. By default, the specified AMI is `ami-bf4193c7`. If the specified AMI is not available to your region, setup will fail.

For more information on AMIs, see [AWS AMI documentation](#).

## Register a domain name with Route53

During configuration, you will be asked to specify a **Public hosted zone ID**. The public hosted zone ID maps to a domain registered with **AWS Route 53**. The domain will be used to form URLs needed for external access to a variety of components in this solution, including applications, and the PingAccess and PingFederate administration consoles.

You can purchase a domain name using Route 53, transfer an existing domain to this service, or [migrate the DNS service for a domain](#).

### Important:

The domain you choose to use for PingAccess admin (**Admin public host name**) and engine nodes (**Applications public host name**), as well as the demonstration PingFederate instance (**PingFederate DNS Name**), **must** be registered with and managed by AWS Route 53. Failure to register or transfer a domain to AWS Route 53 will result in setup failing.

Customers who use an existing PingFederate instance do not need to register the associated domain with AWS Route 53 if:

1. The PingFederate domain is routable via the internet.
2. PingFederate uses a different domain than will be used for PingAccess in AWS.

If an existing PingFederate instance and your PingAccess instances in AWS will use the same root domain, that domain **must** be registered with AWS Route 53.

To learn more about AWS Route 53, including how to [register a domain](#) or transfer an existing domain, see [AWS Route 53 documentation](#).

**Tip:** When your domain name is available in Route 53, make note of the associated **Hosted Zone ID** so you can use it during configuration.

### Create a certificate

During configuration, you will be asked to specify a Certificate ID. The certificate ID will map to a certificate issued for the domain you will use, as specified by the Public hosted zone ID.

You can request a certificate or you can import a certificate using the **AWS Certificate Manager**.

To learn more about AWS Certificate Manager, including how to request or import a certificate, see [AWS Certificate Manager documentation](#).

**Tip:** When your certificate is available in Certificate Manager, make note of the associated **ARN** for the certificate so you can use it during configuration.

### Obtain the automation ZIP file

The first step in creating your PingAccess environment in AWS is to obtain the ZIP file that includes templates and scripts used by the automation process.

Contact your Ping Identity sales representative to obtain the automation ZIP file.

### Create the PingAccess software repository

In order for the automation to run successfully, you must first create a stack that will be referenced by the setup scripts. You will submit a template to [CloudFormation](#) that creates the S3 bucket, and also creates policies that define access to the bucket that are referenced by provisioning functions.

**Important:** Do not manually create the S3 bucket. Use the templates described in this document.

**Prerequisite:** This procedure assumes you have downloaded and unzipped the automation ZIP file.

To create the PingAccess S3 bucket stack and required policies:

1. In the AWS console, navigate to **Services > Management Tools > CloudFormation**.
2. In the CloudFormation console, click **Create Stack**.
3. On the Select Template screen, click to select **Upload a template to Amazon S3**.
4. Click **Choose File**.
5. Navigate to the root of the unzipped archive, select the `create-repo.yaml` template, and click **Open**.
6. Click **Next**.
7. On the **Specify Details** screen, specify the **Stack Name**. For example, `pingaccess-s3-stack`.
8. Specify the **Bucket Name**. For example, `pingaccess-s3-bucket`.

**Important:** Bucket names must be unique **across all of AWS**. If your chosen bucket name is in use, the template will fail.

9. Click **Next**.
10. On the **Options** screen, click **Next**.
11. On the Review screen, click to select the **I acknowledge that AWS CloudFormation might create IAM resources** check box.

12. Click **Create**.

13. When stack creation is complete, view your S3 bucket at **Services > Storage > S3**.

### Populate the S3 bucket

After you create the PingAccess software bucket in S3, you will populate your bucket with the files needed for the automation process. The automation ZIP file you downloaded contains the required directory structure. You will add files to this directory structure and upload a set of folders to S3.

**Note:** Do not modify the directory structure. Modifying the directory structure will cause the setup process to fail.

**Note:** If you are planning to redeploy with an existing configuration, see [Redeploying with an existing configuration](#) on page 270.

### Add files to the directory structure

Prior to uploading to S3, add files that are required for setup. These files include:

- The **Java Server JRE** - Copy the Server JRE install package to `s3-bucket-root/jre/server-jre-<version>-linux-x64.tar.gz`.
- The **PingAccess distribution package** - Copy the PingAccess 5.0.0 or higher distribution package to `s3-bucket-root/pingaccess/dist/pingaccess-<version>.zip`.
- The **PingAccess license file** - Copy the PingAccess license file to `s3-bucket-root/pingaccess/licenses/pingaccess.lic`.
- The **PingFederate distribution package** (Optional) - Copy the PingFederate 8.4.1 or higher distribution package to `s3-bucket-root/pingfederate/dist/pingfederate-<version>.zip` if you are deploying the basic PingFederate instance for a demonstration environment.
- The **PingFederate license file** (Optional) - Copy the PingFederate license file to `s3-bucket-root/pingfederate/licenses/pingfederate.lic` if you are deploying the basic PingFederate instance for a demonstration environment.
- Additional **library JAR files** (Optional) - Copy any additional library JAR files (e.g. plugins) that should be included with the installation to `s3-bucket-root/automation-artifacts/<export-prefix>/pingaccess/lib`, where `<export-prefix>` is the **Export name prefix** you will supply to the [automation template](#).

### Upload the directory structure to S3

1. In the AWS console, navigate to **Services > Storage > S3**.
2. Select the bucket you created.
3. Click **Upload**.
4. In a file window, select the contents of the `s3-bucket-root` folder. The contents include the following folders and their contents:
  - `automation-artifacts`
  - `instance-init-util`
  - `internal-ca`
  - `jre`
  - `pingaccess`
  - `pingfederate`
5. Drag and drop the folders into the AWS **Upload** window.
6. Click **Next** (x3).
7. On the final screen, click **Upload**.

### Create the PingAccess key pair

This solution will require the use of a key pair for SSH access. You can import an existing key pair, use a key pair that already exists in your AWS environment, or you can create new key pair.

### Create a new key pair

1. In AWS, navigate to **Services > Compute > EC2**.
2. In the left menu bar, under the **Network & Security** heading, click **Key Pairs**.

**Tip:** To import an existing key pair, select **Import Key Pair** on the Key Pairs page.

3. Click **Create Key Pair**.
4. Type the **Key pair name** and click **Create**.

The private key is automatically downloaded to your system, while the public key is stored in AWS.

**Important:** Save the private key to a safe location.

### Create the PingAccess VPC

This document provides the steps required to create VPC environment. The automation script includes functions to create all of the required components for this deployment, including:

- PingAccess Administration instance
- PingAccess Engine instances
- Load balancers
- Routing configuration
- Security groups configuration
- PingFederate instance (Optional)

To deploy into an existing VPC, see [Deploy PingAccess into an existing VPC](#) on page 262.

**Important:** If you are planning to deploy the PingAccess for AWS solution along with an existing PingFederate instance, your PingFederate configuration must meet the components requirements expected by the automation. To review the PingFederate configuration requirements, see [PingAccess for AWS: PingFederate environment requirements](#).

**Note:** If you are redeploying with an existing configuration, see [Redeploying with an existing configuration](#) on page 270.

### To create the complete VPC environment:

1. In AWS, navigate to your S3 bucket.
2. Navigate to `/pingaccess/templates` and click on the `create-pingaccess.yaml` template.
3. On the **Overview** tab, copy the template link.
4. Navigate to **Services > Management Tools > CloudFormation**.
5. Click **Create Stack**.
6. Select the option to **Specify an Amazon S3 template URL** and paste the template link you copied.
7. Click **Next**.
8. On the **Specify Details** page, provide the required information using the [Configuration options](#) table as a guide.
9. Click **Next**.
10. **(Optional)** To disable rollback on failure for troubleshooting purposes, on the **Options** page, expand the **Advanced** heading and set **Rollback on failure** to **No**.
11. Click **Next**.
12. On the **Review** page, scroll to the bottom and select **I acknowledge that AWS CloudFormation might create IAM resources with custom names**.
13. Click **Create**.

You will be taken to the **CloudFormation - Stacks** page where you can monitor setup progress. When the setup is successful, the parent stack and all child stacks will show a status of **CREATE\_COMPLETE**.

### Deploy PingAccess into an existing VPC

You can deploy PingAccess into an existing VPC. Follow the same general steps as above, making the following modifications:

**Note:** To create a standalone base VPC, use the `create-base-vpc.yaml` template.

1. Use `pingaccess-setup.yaml` to specify the **Existing VPC ID** and create an **Export Name Prefix** for the PingAccess deployment. This step creates the link between the Export Name Prefix and the existing VPC.
2. Next, use `pingaccess-deploy.yaml` to configure and deploy PingAccess. Use the **Export Name Prefix** you specified in the previous step.

### Configuration options

<b>Stack name</b>	The name of the parent stack. For example: <code>pingaccess-demo</code> .
<b>Export name prefix</b>	The prefix to be applied to all stack outputs imported and exported. For example: <code>pingaccess-stack</code> . You can create multiple clusters by using a unique <b>Export name prefix</b> for each.
<b>Ping S3 repo stack name</b>	The name of the stack used to establish the PingAccess software repository in S3. Use the <b>Stack Name</b> you specified in <a href="#">Create the PingAccess software repository</a> on page 260. For example: <code>pingaccess-s3-stack</code> .
<b>VPC name</b>	The value applied to the VPC Name label. For example: <code>pingaccess-vpc</code> .
<b>VPC CIDR block</b>	The unique network CIDR block to be covered by the created VPC.
<b>Number of public subnets specified</b>	The number of public subnet CIDR blocks to be specified.
<b>Public subnet CIDR blocks</b>	A comma-delimited list of public subnet CIDR blocks. Must be unique subnets of VPC CIDR block.
<b>Availability zones for public subnets</b>	A comma-delimited list of Availability Zones per public subnet. At least two subnets must be in separate Availability Zones.
<b>Number of private subnets specified</b>	The number of private subnet CIDR blocks to be specified.
<b>Private subnet CIDR blocks</b>	A comma-delimited list of private subnet CIDR blocks. Must be unique subnets of VPC CIDR block.
<b>Availability zones for private subnets</b>	A comma-delimited list of Availability Zones per private subnet. At least two subnets must be in separate Availability Zones.
<b>The allowed tenancy of instances launched into the VPC</b>	The allowed tenancy of instances launched into the VPC.
<b>Admin Node Private Host Name</b>	The admin node host name to associate with the internal ELB.
<b>Internal private domain name</b>	The domain name to use for the private hosted zone for Ping Identity infrastructure internal DNS names. For example: <code>pingaccess.aws</code> .

<b>Public hosted zone ID</b>	The public hosted zone for use with external Route 53 DNS. You must have a public domain name registered with Amazon Route53. For more information, see <a href="#">Route53 documentation</a> . For example: <code>my-aws-domain.com</code> .
<b>Admin public host name</b>	The fully qualified domain name to associate with the internet facing ELB for the admin API. This should be a unique subdomain of the specified Public hosted zone ID. This entry <b>must</b> be followed by a period. For example: <code>admin.my-aws-domain.com</code> .
<b>Applications public host name</b>	The fully qualified domain name to associate with the internet facing ELB for the engines. This should be a unique subdomain of the specified Public hosted zone ID. This entry <b>must</b> be followed by a period. For example: <code>app.my-aws-domain.com</code> .
<b>PingAccess Admin API port</b>	The TCP/IP port of the PingAccess Admin API listener. Use the default of 9000.
<b>PingAccess configuration query port</b>	The TCP/IP port of the Admin Config Query listener. Use the default of 9090.
<b>SSH port</b>	The TCP/IP port for the VPC bastion host and PingAccess instance SSH access. Use the default of 22.
<b>EC2 keypair name</b>	The EC2 Key Pair for SSH access to the VPC bastion host and PingAccess instances. Use the key pair you created or imported.
<b>Bastion host AMI ID</b>	The Amazon Linux AMI ID for the bastion host. The default AMI is for US West (Oregon).
<b>Bastion host instance type</b>	The EC2 instance type for the bastion host. Use the default of <code>t2.micro</code> or higher.
<b>Admin AMI ID</b>	The Amazon Linux or RHEL 7.4 AMI ID for Admin instances. The default AMI is for US West (Oregon).
<b>Admin instance type</b>	The EC2 instance type for Admin nodes. Use the default of <code>m3.large</code> or higher.
<b>Administrative node root volume name</b>	The root volume device name for the specified Admin AMI. Commonly, Amazon Linux uses <code>/dev/xvda</code> and RHEL 7.4 uses <code>/dev/sda1</code> .
<b>Administrative node root volume size</b>	The size, in GB, for the root volume on the Admin instance. Use the default of 15 or higher.
<b>Engine AMI ID</b>	The Amazon Linux or RHEL 7.4 AMI ID for Engine node instances. The default AMI is for US West (Oregon).

<b>Engine instance type</b>	The EC2 instance type for Engine nodes. Use the default of <code>m3.large</code> or higher.
<b>Engine node root volume name</b>	The root volume device name for the specified Engine AMI. Commonly, Amazon Linux uses <code>/dev/xvda</code> and RHEL 7.4 uses <code>/dev/sda1</code> .
<b>Engine node root volume size</b>	The size, in GB, for the root volume on Engine instances. Use the default of 16 or higher.
<b>Engine node root volume IOPS</b>	The provisioned IOPS for the root volume on Engine instances. The maximum ratio of IOPS to volume size is 50:1.
<b>Internal CA AMI ID</b>	Amazon Linux AMI ID for the Internal CA. The default AMI is for US West (Oregon).
<b>PingFederate AMI ID</b>	Amazon Linux AMI ID for PingFederate. The default AMI is for US West (Oregon). This parameter is only used when <code>ProvisionPingFederate</code> is true.
<b>Admin API certificate ID (ARN)</b>	The ARN of the certificate to use with Admin API ELB listener. Use the certificate you created or imported.
<b>Engines application certificate ID (ARN)</b>	The ARN of the certificate to use with Engine API ELB listener. Use the certificate you created or imported.
<b>Internal CA hostname</b>	The unqualified hostname for the Internal CA within the private hosted zone.
<b>Root CA Certificate TTL</b>	The amount of time that the Root CA certificate will be valid before it expires. The default is 20 years (20y).
<b>Certificate Generation Token TTL</b>	Time to live for Vault tokens issued for certificate generation. The default is 1 year (1y).
<b>Leaf Certificate Default TTL</b>	The default time to live for generated leaf certificates before they expire. The default is 30 days (30d).
<b>Leaf Certificate Max TTL</b>	The maximum time to live allowed for leaf certificate generation requests.
<b>Certificate Renewal Threshold</b>	The number of days before a certificate expires that it should be renewed.
<b>Certificate Renewal Schedule</b>	The schedule expression that determines how often checks for certificate renewal should occur. For more information, see <a href="#">AWS documentation for scheduled events</a> .

<b>Provision PingFederate</b>	<p>Specify whether or not you want to provision a PingFederate instance.</p> <ul style="list-style-type: none"> <li>• Select <b>True</b> to provision a PingFederate instance in the demonstration environment.</li> <li>• Select <b>False</b> to use an existing PingFederate instance. If you select <b>False</b>, you must ensure your PingFederate configuration meets the requirements expected by the automation. To review the required PingFederate setup, see PingAccess for AWS: PingFederate environment requirements.</li> </ul>
<b>PingFederate Version</b>	<p>Indicates the PingFederate version expected in the S3 repository file name pingfederate-<b>&lt;PingFederateVersion&gt;</b> .zip. For example, pingfederate- <b>8.4.4</b> .zip.</p> <p>This field is ignored if <b>Provision PingFederate</b> is set to <b>False</b>.</p>
<b>PingFederate DNS Name</b>	<p>The fully qualified domain name to associate with the internet facing PingFederate instance. This should be a unique subdomain of the specified Public hosted zone ID. This entry <b>must</b> be followed by a period.</p> <p>For example: pf.my-aws-domain.com.</p> <p>This field is ignored if <b>Provision PingFederate</b> is set to <b>False</b>.</p>
<b>PingFederate Admin API Port</b>	<p>The PingFederate Admin API port. Use the default of 9999.</p> <p>This field is ignored if <b>Provision PingFederate</b> is set to <b>False</b>.</p>
<b>PingFederate Runtime Port</b>	<p>The PingFederate Runtime port. Use the default of 9031.</p> <p>This field is ignored if <b>Provision PingFederate</b> is set to <b>False</b>.</p>
<b>PingAccess Audit Logs Retention</b>	<p>The number of days to retain CloudWatch audit logs.</p>
<b>PingAccess Server Logs Retention</b>	<p>The number of days to retain CloudWatch server logs.</p>
<b>Lambda Logs Retention</b>	<p>The number of days to retain CloudWatch Lambda logs.</p>
<b>Java version</b>	<p>Indicates the Java JRE version expected in the S3 repository file name server-jre-8u <b>&lt;JavaVersion&gt;</b> -linux-x64.tar.gz. For example, server-jre-8u <b>151</b> -linux-x64.tar.gz.</p>

<b>PingAccess Version</b>	Indicates the PingAccess version expected in the S3 repository file name pingaccess- <b>&lt;PingAccessVersion&gt;</b> .zip. For example, pingaccess- 5.0.0 .zip.
---------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------

### Configure Security Groups

To access the PingAccess and PingFederate Administration consoles, as well as the PingFederate runtime, AWS Security Groups must be configured to allow ingress traffic on the required ports. The complete installation provides a set of Security Groups that you must configure.

You can:

- [Configure the included security groups for ingress access](#)
- [Create a new Security Group](#)

**Important:** By default, all security groups created as part of this solution are configured to allow **all** egress traffic. Administrators may wish to review egress traffic requirements for their network and modify these settings. For more information, see [AWS documentation for Security Groups](#).

#### Configure the included security groups for ingress access:

1. In AWS, navigate to **Services > Compute > EC2**.
2. In the left menu bar, under **Network & Security**, click **Security Groups**.
3. Select the Security Group you want to edit. See the table below for the list of groups.
4. In the bottom pane that appears, select the **Inbound** tab.
5. Click **Edit**.
6. In the **Edit inbound rules** window, click **Add Rule**.
  - a. Add a **Custom TCP** rule.
  - b. In the **Port Range** field, enter the port. See the table below for required ports.
  - c. Enter the CIDR or IP for the machine you want to use for access. For quick access, you can select the **Source of My IP**.
7. Click **Save**.

<b>PingAccess Admin API ingress</b>	Port 9000
<b>PingFederate</b>	Ports 9999 and 9031
<b>SSH Ingress</b> (Type SSH)	Port 22

**Note:** Configuration of PingFederate Security Groups is only required if you are choosing to deploy with a demonstration PingFederate instance by selecting "True" for the ProvisionPingFederate parameter in the PingAccess for AWS CloudFormation template.

#### Create a new Security Group:

1. In AWS, navigate to **Services > Compute > EC2**.
2. Create a Security Group and assign it to the VPC that will include the PingAccess and PingFederate installations.
3. Add 3 **Custom TCP** rules and one **SSH** rule:
  - Port Range: **9000**, Source: **My IP**
  - Port Range: **9999**, Source: **My IP**
  - Port Range: **9031**, Source: **My IP**
  - Post Range: **22**, Source **My IP**
4. Click **Create**.

### Access the PingAccess administration console

After the automated deployment is complete, you can access the PingAccess administrative console. The PingAccess administrative console will allow you to configure a token provider, create sites and applications, configure policies, and perform other related tasks.

**Important:** The PingAccess for AWS solution protects your admin node availability by ensuring a new instance of the admin node is created automatically in the event of a failure. This automated process deploys an instance of the PingAccess admin node based on the settings specified in `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`.

For this reason, it is **critical** to your deployment that you maintain this file. Any time changes are made to the PingAccess configuration, you **must** export the new configuration and replace the existing file at `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`. Failure to synchronize this file could lead to unexpected results if your admin node should fail for any reason.

### Access the PingAccess Administration console

To access the PingAccess Administration console in your browser, use a combination of the Admin public host name and the PingAccess Administration port.

For example: `https://pa-admin.mypublichostname.com:9000`

For the demonstration environment, use the following credentials:

```
Username: joe
Password: 2Federate
```

If you are using an existing PingFederate instance, login with the credentials you created for use with the Simple Password Credential Validator in [PingAccess for AWS: PingFederate environment requirements](#).

### Access the PingFederate administration console

**Note:** The following instructions only apply if you have chosen to deploy the PingAccess for AWS solution with a basic PingFederate instance for demonstration purposes.

After the automated deployment is complete, you can access the PingFederate administrative console. The PingFederate administrative console will allow you to configure clients and perform other related tasks.

### Access the PingFederate Administration console

To access the PingFederate Administration Console in your browser, use a combination of the PingFederate public host name, the PingFederate Administration port, and the path to the PingFederate application.

For example: `https://pf-admin.mypublichostname.com:9999/pingfederate/app`

For this demonstration, use the default PingFederate credentials:

```
Username: Administrator
Password: 2Federate
```

### Configure SSH connectivity

Configure SSH connectivity to the PingAccess Administration and Engine nodes so you can perform tasks such as viewing logs. The PingAccess Administration and Engine nodes are not exposed directly to the internet, but are configured to be placed behind a Bastion host through which you can access these resources. You first connect to the Bastion host, and then establish a connection to the desired resource.

The instructions provided here are intended to detail just one of the methods you can use to establish this connectivity. You may choose to use another method.

### Prerequisites

This procedure requires that you have the following:

- The PingAccess private key
- The Public DNS hostname used by the Bastion host. Obtain this in EC2 by selecting the SSH Bastion instance and viewing the Description tab.
- The Private DNS hostname used by the PingAccess Admin Console and/or Engines. Obtain this in EC2 by selecting the desired instance and viewing the Description tab.

### Configure SSH connectivity

1. Add the PingAccess private key to the SSH authentication agent. Run this command from the directory containing the private key. For example:

```
ssh-add -K ~/.ssh/mypingaccesskeypair.pem
```

2. Add a host entry to your SSH configuration for the Bastion host. You will provide a name for the entry, the public DNS host name, and the user name used to access the host. For example, use the GNU nano editor to edit the host file with the following command:

```
nano ~/.ssh/config
```

Add an entry with the following information:

```
Host aws-bastion
    Hostname mypublicbastiondns.compute.amazonaws.com
    User ec2-user
```

Save the file.

3. Test the connection to the Bastion host:

```
ssh aws-bastion
```

4. Add one or more SSH host entries for the Administration or Engine nodes, as required. Use the ProxyCommand function to route the connection through the Bastion host. For example:

```
Host aws-console
    Hostname myinternaladmindns.compute.internal
    ProxyCommand ssh -q aws-bastion nc %h 22
    User ec2-user
```

Save the file.

### Establish a connection

Establish a connection to a configured PingAccess Administration or Engine node using the name you configured in the SSH host file. For example:

```
ssh aws-console
```

### View PingAccess log files

To assist with troubleshooting, you can view PingAccess Admin and Engine log files. You can view logs related to the admin or engine nodes, and you can view [AWS CloudWatch](#) logs. To view node log files, you must first [establish an SSH connection](#) to the required node.

On an Admin or Engine node, the PingAccess installation can be found at `/usr/local/pingaccess`. Log files are contained in the `log` directory.

### View log files

After you have established a connection to the node, navigate to the proper directory and open the file using an editor such as GNU nano. For example:

```
cd /usr/local/pingaccess/log
nano pingaccess.log
```

### Maintaining the S3 bucket

To maintain the S3 bucket for updated files, simply delete the existing files and upload any new files using the steps found in [Populate the S3 bucket](#) on page 261.

**Note:** If you are planning to redeploy with an existing configuration, see [Redeploying with an existing configuration](#) on page 270.

### Delete the PingAccess VPC

If removal of the PingAccess VPC is required, you can perform this task by deleting the top level stack. To do this:

1. In AWS, navigate to **Services > Management Tools > CloudFormation**.
2. In the CloudFormation console, select the top level template.
3. Click **Actions > Delete Stack**.
4. When prompted, confirm the operation.

**Note:** If you are planning to redeploy with an existing configuration, see [Redeploying with an existing configuration](#) on page 270.

### Redeploying with an existing configuration

You can redeploy the PingAccess for AWS solution using an existing configuration. You can specify to use an existing configuration by re-using the **Export name prefix**. Customers who wish to redeploy while maintaining an existing configuration should consider the following notes:

- You must first delete the PingAccess VPC
- When redeploying, you must use the same **Export name prefix**.
- Before you begin, you must delete the engine definitions present at `/automation-artifacts/<exportnameprefix>/pingaccess/engines`.
- If you intend to change certificate related parameters, you must delete the `/automation-artifacts/<exportnameprefix>/ca` folder.

### Troubleshooting setup

For a variety of possible reasons, you can encounter errors or other issues during the creation of the PingAccess environment. This document is intended to provide guidance on troubleshooting some of these issues.

To troubleshoot setup, you should [disable Rollback on Failure](#) so that relevant logs and other helpful information remain available.

- [General](#)
- [Viewing logs on EC2 instances](#)
- [View CloudWatch logs](#)
- [View Lambda functions](#)
- [Modify templates to support Signature Version 4](#)

### General

Some of the more common errors come from the planning and/or preparation process. For your chosen deployment type, ensure that you have provided and specified:

- Valid license files for PingAccess and, if applicable, PingFederate
- Valid installation packages for PingAccess and, if applicable, PingFederate

- Valid Server JRE install package
- A set of [AMIs](#) available to your AWS region that support Signature Version 2
- One or more [certificates](#) available to your AWS region
- If you are redeploying and reusing the same Export Name Prefix, ensure you have followed the advice in [Redeploying with an existing configuration](#) on page 270.

### Viewing logs on EC2 instances

To view CloudFormation logs on your EC2 instances, [SSH to the instance](#) and view logs located at `/var/log`. CloudFormation logs begin with the `cfn-` prefix.

For instances that contain a PingAccess or PingFederate installation, you can view their respective log files at `/usr/local/pingaccess/log` and `/usr/local/pingfederate/log`.

### View CloudWatch logs

CloudWatch logs sometimes contain helpful information in the event of a failure. View CloudWatch logs by navigating to **Services > Management Tools > CloudWatch** and clicking **Logs**.

You can filter logs for easier viewing. To find applicable CloudWatch logs, filter using the string `/pingidentity/{ExportNamePrefix}` where `{ExportNamePrefix}` is replaced by the **Export name prefix** you specified during [VPC creation](#).

Click on a log group to view available log streams and their contents. To learn more about CloudWatch logs, see [AWS documentation for CloudWatch logs](#).

### View Lambda functions

To help narrow down causes for an issue, it may be helpful to view logged details for the lambda that is producing the error. To do this, navigate to **Services > Compute > Lambda** and filter by the VPC name. Locate and click the lambda function you are investigating. On the **Monitoring** tab, review the **Invocation errors** widget and click **Jump to Logs**.

### Modify templates to support Signature Version 4

[Some regions do not support](#) Signature Version 2. In release 1.0, if you select a region that does not support Signature Version 2, you must to modify the templates to use Signature Version 4 style URLs. Since many templates are configured to use Signature Version 2 style URLs, the simplest way to make the required change is to find and replace through all files stored in the automation directory.

Find the string `https://${BUCKET_NAME}.s3.amazonaws.com/` and replace it with `https://s3-${AWS::Region}.amazonaws.com/${BUCKET_NAME}/`.

**Note:** This workaround is not required in release 1.0.1 or above.

## Configure an Application for PingAccess for AWS

### Introduction

You can configure a protected application in the PingAccess for AWS environment. This document will provide instructions for configuring an application. These instructions are applicable for deployments that include a basic PingFederate instance, as well as deployments that make use of an existing PingFederate environment.

These instructions assume you have successfully deployed your environment and are able to access the PingAccess and PingFederate administration consoles.

**Important:** The PingAccess for AWS solution protects your admin node availability by ensuring a new instance of the admin node is created automatically in the event of a failure. This automated process deploys an instance of the PingAccess admin node based on the settings specified in `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`.

For this reason, it is **critical** to your deployment that you maintain this file. Any time changes are made to the PingAccess configuration, you **must** export the new configuration and replace the existing file at

automation-artifacts/<export\_prefix>/pingaccess/conf/pingaccess.json. Failure to synchronize this file could lead to unexpected results if your admin node should fail for any reason.

## Protect an application

This document provides the steps required to protect an application using PingAccess and PingFederate in the AWS environment.

To protect an application, complete the following steps:

1. [Configure PingFederate](#) on page 272
2. [Configure a PingAccess web application](#) on page 273
3. [Configure a PingAccess API application](#) on page 275
4. [Test the web application](#) on page 276
5. [Test the API application](#) on page 276

## Install and access the unprotected PingAccess QuickStart application

After the automated deployment is complete, you can install the PingAccess QuickStart application. The PingAccess QuickStart application can be used to test a protected PingAccess application.

### Install the PingAccess QuickStart application

To install the PingAccess QuickStart application:

1. Download the PingAccess QuickStart application.
2. Unzip the file.
3. Copy `\pingaccess-quickstart-<version>\pf-dist\PingAccessQuickStart.war` to `<PingFedHome>\pingfederate\server\default\deploy`.
4. Restart PingFederate.

### Access the unprotected PingAccess QuickStart application

To access the unprotected PingAccess QuickStart application in your browser, use a combination of the PingFederate public host name, the PingFederate runtime port, and the path to the QuickStart application.

For example: `https://pf-admin.mypublichostname.com:9031/PingAccessQuickStart`

## Configure PingFederate

If you have deployed a basic PingFederate instance as part of the automation process, most of the configuration is complete. Likewise, if you have deployed with an existing PingFederate instance, and meet the PingFederate environment requirements, most of the required configuration is complete.

This document describes the steps required to create a client that will be used for the PingAccess Web Session you will assign to a web based application in PingAccess.

### To create the web session client in PingFederate:

1. Log in to the PingFederate administration console.
2. Navigate to **Main > OAuth Settings > Clients** and click **Manage All**.
3. Click **Add Client**.
4. Specify a **Client ID**. For example:

```
pa_wam
```

5. Specify a **Name**. For example:

```
PingAccessWebAccessManagement
```

6. Select **Client Secret**.
7. Generate a secret by clicking **Generate Secret**. Copy this secret to a secure location so that you can use it in PingAccess configuration.

8. In the **Redirection URIs** field, add the OIDC callback redirect to the PingAccess server, for example:

```
https://mypingaccessserver.my-aws-domain.com/pa/oidc/cb
```

9. Click **Add**.

10. Select the **Bypass Authorization Approval** check box.

11. For the **Allowed Grant Type** setting, select the **Authorization Code** check box.

12. Click **Save** (x2).

### Configure a PingAccess web application

This document provides the steps required to configure the demo web application in PingAccess. In performing the steps required, you will:

1. [Create a web session](#) on page 273
2. [Create a virtual host](#) on page 273
3. [Create a site](#) on page 274
4. [Create an application](#) on page 274
5. [Configure resources](#)

**Important:** The PingAccess for AWS solution protects your admin node availability by ensuring a new instance of the admin node is created automatically in the event of a failure. This automated process deploys an instance of the PingAccess admin node based on the settings specified in `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`.

For this reason, it is **critical** to your deployment that you maintain this file. Any time changes are made to the PingAccess configuration, you **must** export the new configuration and replace the existing file at `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`. Failure to synchronize this file could lead to unexpected results if your admin node should fail for any reason.

### Create a web session

Create a web session to control access. For more information, see [Web Sessions](#).

1. Navigate to **Settings > Access > Web Sessions**
2. On the Web Session page, click **Add Web Session**.
3. Enter a unique **Name** for the web session, up to 64 characters, including special characters and spaces. For example:

```
PF_WAM
```

4. Select `Encrypted JWT` for **Cookie Type**.
5. Specify the **Audience** that the PA Token is applicable to, represented as a short, unique identifier between 1 and 32 characters. For example:

```
global
```

6. Specify the **OpenID Connect Login Type** `CODE`.
7. Specify the **Client ID**. For example, the Client ID you created is:

```
pa_wam
```

8. Specify the **Client Secret** you copied in [Configure PingFederate](#) on page 272.

9. Click **Save**.

### Create a virtual host

Create a virtual host that PingAccess will respond to. For more information, see [Virtual Hosts](#).

1. Navigate to **Settings > Access > Virtual Hosts**.

2. Click **Add Virtual Host**.
3. Enter the **Host** name for the Virtual Host or specify a wildcard. For example: `app.my-aws-pingaccess.com` OR `*`.
4. Enter the **Port** number for the Virtual Host. In this environment, AWS is expecting a secure connection, so you must specify the secure port. For example:

```
443
```

5. Click **Save**.

### Create a site

Create a site to define the location of the application that PingAccess is protecting. For more information, see [Sites](#).

1. Navigate to **Main > Sites > Sites**.
2. Click **Add Site**.
3. Specify a **Name**. For example:

```
QuickStart
```

4. Specify the **Target**. The format for this is `hostname:port`. For example:

```
pf.my-pf-instance.com:9031
```

5. Select **Secure** and choose the `Trust Any` **Trusted Certificate Group**.
6. Click **Save**.

**Note:** If the target site cannot be contacted, the site is saved and a warning is displayed indicating the reason the site was not reachable.

### Create an application

Create an application to define the resource that PingAccess is protecting. For more information, see [Applications](#).

1. Navigate to **Main > Applications**.
2. Click **Add Application**.
3. Provide a unique name for the application. For example:

```
QuickStart
```

4. Specify the context at which the application is accessed at the site. For example:

```
/PingAccessQuickStart
```

5. Specify the virtual host for the application. For example:

```
*:443
```

6. Specify the application type `web` and select the **Web Session** for the application. For example:

```
PF_WAM
```

7. Specify the application destination type `Site` and select the **Site** requests are sent to when access is granted. For example:

```
QuickStart
```

8. Select the **Require HTTPS** option.
9. Select the **Enabled** checkbox.

10. Click **Save**.

### Configure resources

**Note:** This step is only required for the demonstration environment. Your resource access requirements may differ.

Configure application resources to allow anonymous access to the root resource and authenticated access to the `/headers` resource.

1. Navigate to **Main > Applications**.
2. Expand the QuickStart application and click the edit button.
3. Select the **Resources** tab.
4. Expand the **Root Resource** and click the edit button.
5. Select the **Anonymous** checkbox and click **Save**.
6. Click **Add Resource**.
7. Enter a **Name** for the resource. For example: `headers`.
8. Enter the **Path Prefix** of `/headers`.
9. Click **Save**.

### Configure a PingAccess API application

This document provides the steps required to configure the demo API application in PingAccess. Prior to completing these steps, ensure you have followed the steps in [Configure a PingAccess web application](#) on page 273 to create a **Virtual Host** and a **Site**.

**Important:** The PingAccess for AWS solution protects your admin node availability by ensuring a new instance of the admin node is created automatically in the event of a failure. This automated process deploys an instance of the PingAccess admin node based on the settings specified in `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`.

For this reason, it is **critical** to your deployment that you maintain this file. Any time changes are made to the PingAccess configuration, you **must** export the new configuration and replace the existing file at `automation-artifacts/<export_prefix>/pingaccess/conf/pingaccess.json`. Failure to synchronize this file could lead to unexpected results if your admin node should fail for any reason.

### Create an application

Create an application to define the resource that PingAccess is protecting. For more information, see [Applications](#).

1. Navigate to **Main > Applications**.
2. Click **+ Add Application**.
3. In the **Name** field, enter a unique name for the application. For example:

```
QuickStart
```

4. In the **Context Root** field, enter the context at which the application is accessed at the site. For example:

```
/PingAccessQuickStart/api
```

5. In the **Virtual Host(s)** dropdown, specify the virtual host for the application. For example:

```
* : 443
```

6. In the **Application Type** dropdown, select **API**.
7. In the **Access Validation** dropdown, select **Token Provider**.

- Specify the application destination type **Site** and select the **Site** requests are sent to when access is granted. For example:

```
QuickStart
```

- Select the **Require HTTPS** check box.
- Select the **Enabled** check box.
- Click **Save**.

### Test the web application

This document describes the steps to test the demo web application.

**Tip:** For the most visible experience with this demo, perform these steps in a new private or incognito session to avoid the reuse of an existing session.

#### To test the web application:

- Open your browser and navigate to the application using a combination of the **Applications public host name** you created in [Create the PingAccess VPC](#) on page 262 and the application Context Root. For example:

```
https://app.my-aws-domain.com/PingAccessQuickStart
```

- On the Web Access Management application, click **Try it Now**.
- You will be prompted to authenticate. Enter the **Username** and **Password** combination included with the QuickStart demo application: `joe/2Federate`.

The **headers** page is displayed.

### Test the API application

This document describes the steps to test the demo API application.

**Tip:** For the most visible experience with this demo, perform these steps in a new private or incognito session to avoid the reuse of an existing session.

#### To test the demo API application:

- Open your browser and navigate to the application using a combination of the **Applications public host name** you created in [Create the PingAccess VPC](#) on page 262 and the application Context Root. For example:

```
https://app.my-aws-domain.com/PingAccessQuickStart
```

- On the API Access Management application, click **Try it Now**.
- Click the **Get Token** button.
- You will be prompted to authenticate. Enter the **Username** and **Password** combination included with the QuickStart demo application: `joe/2Federate`.

The token is obtained and pre-populated along with the URL context.

- Click **Send API Request**.

A **Response Code** of **200** indicates a successful test. **Response Headers** are displayed.

## PingAccess for Azure AD

---

### Solution overview

This document provides the steps required to configure PingAccess as part of the use case to provide secure external access to legacy on-premises applications using PingAccess for Azure AD and Microsoft Azure AD.

In this scenario, PingAccess provides an external path to legacy on-premises applications via the Azure AD Application Proxy through the use of header based authentication. Additionally, Microsoft Azure AD acts as the token provider for associated sessions.

PingAccess for Azure AD is a limited, free version of PingAccess for Microsoft Azure AD customers that provides protection for up to 20 applications.

This solution requires you to perform the following tasks. For more information about the requirements and options available for each task, review the task.

- [Configure PingAccess to use Azure AD as the token provider](#)
- [Configure a PingAccess application](#) for each application you want to protect and make available to Azure AD as part of this solution. Applications require configuration of:
  - A virtual host
  - A web session
  - An identity mapping
  - A site
  - An application

When the configuration is complete, you can test the application using the **Home Page URL** that you create in Azure AD.

## Configure PingAccess to use Azure AD as the token provider

You can configure PingAccess to use Azure AD as the token provider.

**Tip:** For more information on configuring the token provider, see [Configure a token provider](#).

### Assumptions

- You have installed PingAccess and can access the [Administrative console](#). For information on installing PingAccess, see [Install PingAccess](#).

**Note:** The default credential set should be changed upon first usage. The default credentials for your PingAccess installation are:

```
Username: Administrator
Password: 2Access
```

- If your administrative node uses a proxy for HTTP requests to the token provider, you have selected the HTTP Proxy in the **System > Clustering** section. See [Configure the primary administrative node](#) for more information.

### Configure the token provider

1. Navigate to **Settings > System > Token Provider**.
2. In the **Issuer** field, enter the Microsoft Azure AD **Directory ID**. To obtain the Directory ID from Azure AD, in the Azure AD directory, navigate to **Manage > Properties** and copy the **Directory ID** value.
3. Provide a **Description** of the token provider.
4. In the **Trusted Certificate Group** list, select **Java Trust Store** or **Trust Any**.
5. Click **Save**.
6. To get the most out of the solution, configure [token provider specific options](#).

## Configure a PingAccess application

This document describes the steps required to configure PingAccess applications so that they are accessible to users via the Microsoft Azure [MyApps](#) portal. Use these instructions for each application that you want to configure.

### Assumptions:

- You have installed PingAccess and can access the [Administrative console](#). For information on installing PingAccess, see [Install PingAccess](#).

**Note:** The default credential set should be changed upon first usage. The default credentials for your PingAccess installation are:

```
Username: Administrator
Password: 2Access
```

- You have a [Microsoft Azure AD](#) Premium account for access to the Application Proxy feature.
- You have performed configuration in Microsoft Azure AD. For steps to configure Microsoft Azure AD, see <https://docs.microsoft.com/azure/active-directory/application-proxy-ping-access>.
- PingAccess is [configured](#) to use Azure AD as the token provider.

### Create a virtual host

**Tip:** For more information on creating a virtual host, see [Create a virtual host](#).

**Important:** In a typical configuration for this solution, you will create a virtual host for every application. For more information regarding configuration considerations and their impacts, see [Key considerations](#).

- Navigate to **Settings > Access > Virtual Hosts**.
- Click **Add Virtual Host**.
- In the **Host** field, enter the FQDN portion of the Azure AD **External URL**. For example, external URLs of `https://app-tenant.msapproxy.net/` and `https://app-tenant.msapproxy.net/AppName` will both demand a Host entry of `app-tenant.msapproxy.net`.
- In the **Port** field, enter 443.
- Click **Save**.

### Create a web session

**Tip:** For more information on creating a web session, see [Create a web session](#).

- Navigate to **Settings > Access > Web Sessions**.
- Click **Add Web Session**.
- Provide a **Name** for the web session.
- Select the **Cookie Type**, either **Signed JWT** or **Encrypted JWT**.
- Provide a unique value for the **Audience**.
- In the **Client ID** field, enter the Azure AD **Application ID**.
- In the **Client Secret** field, enter the **Key** you generated for the application in Azure AD.
- (Optional)** You can create and use custom claims with the Azure AD GraphAPI. If you choose to do so, click **Advanced** and deselect the **Request Profile** and **Refresh User Attributes** options. For more information on using custom claims, see [Optional - Use a custom claim](#).
- Click **Save**.

### Create an identity mapping

**Tip:** For more information on creating an identity mapping, see [Create an identity mapping](#).

**Note:** An identity mapping can be used with more than one application if more than one application is expecting the same data in the header.

- Navigate to **Settings > Access > Identity Mappings**.
- Click **Add Identity Mapping**.
- Specify a **Name**.
- Select the identity mapping **Type** of **Header Identity Mapping**.
- In the **Attribute Mapping** table, specify the required mappings. For example:

Attribute Name	Header Name
upn	x-userprinciplename
email	x-email
oid	x-oid
scp	x-scope
amr	x-amr

6. Click **Save**.

**Tip:** For more information about Azure AD tokens and for a list of supported claims, see <https://docs.microsoft.com/en-us/azure/active-directory/develop/active-directory-token-and-claims>.

**Important:** This use case only supports the claims discussed at the location included in the **Tip**.

### Create a site

**Tip:** For more information on creating a site, see [Create a site](#).

**Note:** In some configurations, it is possible that a site may contain more than one application. A site can be used with more than one application, where appropriate.

1. Navigate to **Main > Sites > Sites**.
2. Click **Add Site**.
3. Specify a **Name** for the site.
4. Enter the site **Target**. The target is the hostname:port pair for the server hosting the application. Do not enter the path for the application in this field. For example, an application at `https://mysite:9999/AppName` will have a target value of `mysite:9999`.
5. Indicate whether or not the target is expecting **Secure** connections.
6. If the target is expecting secure connections, set the **Trusted Certificate Group to Trust Any**.
7. Click **Save**.

### Create an application

You will create an application in PingAccess for each application in Azure that you want to protect.

**Tip:** For more information on creating an application, see [Create an application](#).

1. Navigate to **Main > Applications**.
2. Click **Add Application**.
3. Specify a **Name** for the application.
4. Optionally, enter a **Description** for the application.
5. Specify the **Context Root** for the application. For example, an application at `https://mysite:9999/AppName` will have a context root of `/AppName`. If the application is on the root of the server, you can set the context root as `/`. The context root must begin with a slash (`/`), must not end with a slash (`/`), and can be more than one layer deep, for example, `/Apps/MyApp`.
6. Select the **Virtual Host** you created.
 

**Note:** The combination of Virtual Host and Context Root must be unique in PingAccess.
7. Select the **Web Session** you created.
8. Select the **Site** you created that contains the application.
9. Select the **Identity Mapping** you created.
10. Select **Enabled** to enable the site when you save.
11. Click **Save**.

## Getting started with PingAccess for Azure AD

This document provides information to get you started with the solution to protect legacy on-premises applications using **Microsoft Azure AD** and a limited version of PingAccess called **PingAccess for Azure AD**.

There are a variety of considerations that should be made when planning for a successful deployment.

### Plan your deployment type and architecture

Use the [Deployment reference guide](#) to plan your deployment type and architecture. Learn about the differences between and benefits of a proxy deployment versus an agent based deployment, and decide to use one or a combination of both deployment types.

### Design and plan a PingAccess cluster

Use the [Clustering reference guide](#) to design and plan your PingAccess cluster. For a high availability deployment, use a cluster that contains both a primary administrative node and a replica administrative node, along with additional engine nodes. For best performance, employ a [load balancing strategy](#).

### Install PingAccess

Ensure your systems meet the requirements so you can [Install PingAccess](#).

### Tune performance

Use the [Performance tuning reference guide](#) to configure your deployment for optimal performance.

### Configure logging

[Configure logging](#) so that you can monitor your PingAccess deployment and troubleshoot application issues.

### Configure the PingAccess token provider

Configure PingAccess to use Microsoft Azure AD as the [token provider](#). Perform optional additional configuration that allows for communication with the [Azure AD Graph API](#).

### Configure applications

[Configure applications](#) to be made available by PingAccess to the Microsoft **MyApps** portal via Azure AD using the **Azure AD Application Proxy**.

### Configure for dual internal and external secure access

[Configure the solution](#) so that applications are made securely available both externally through the Microsoft **MyApps** portal and internally through **PingAccess for Azure AD**.

## PingAccess for Azure AD: Configure dual internal and external secure access

This document describes the steps necessary to configure applications for secure access both from inside the network and from outside.

1. Configure an application for secure external access using [Microsoft Azure AD](#) and [PingAccess for Azure AD](#). Ensure that the application is functioning as expected.
2. In **PingAccess**, create a new [Virtual Host](#) that maps to the PingAccess host. For example, `<PingAccessServerName> : 3000`.
3. Assign the new virtual host to the application in addition to the virtual host specified for Azure access.
4. In **Azure AD**, navigate to the App Registrations page and select the application.
5. Click **Reply URLs**, and add the internal PingAccess reply URL. For example, `<PingAccessServerName> : 3000/pa/oidc/cb`.
6. Save the changes and test the configuration.

## PingAccess Agent for Apache (RHEL)

### Introduction

The PingAccess Agent for Apache is an Apache module that intercepts requests to the web server's protected resources and evaluates applicable access control policies. These policies are evaluated by either accessing a locally cached policy decision or by querying the PingAccess engine node.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

Within the PingAccess Administration Console, agent nodes are configured with information that allows a PingAccess Agent to connect to the engine node to retrieve information about access control policies for resources within that agent's control. An agent configuration has a one-to-many relationship with PingAccess agents, allowing a single agent configuration bootstrap file to be used on multiple web servers within a server farm.

**Tip:** An agent node is a shared configuration used by one or more agents, rather than a specific agent instance.

## System Requirements

The PingAccess Agent for Apache is supported on the following platforms:

- Apache HTTP Server 2.2 running on RedHat Enterprise Linux Server 6 (x86\_64)
- Apache HTTP Server 2.2 running on RedHat Enterprise Linux Server 7 (x86 and x86\_64)
- Apache HTTP Server 2.4 running on RedHat Enterprise Linux Server 6 (x86\_64)
- Apache HTTP Server 2.4 running on RedHat Enterprise Linux Server 7 (x86\_64)
- IBM HTTP Server 8.5 running on RedHat Enterprise Linux Server 6 (x86\_64)
- IBM HTTP Server 9.0 running on RedHat Enterprise Linux Server 7 (x86\_64)

As with any system that is reachable from the Internet, the server should be properly hardened. The PingAccess Agent for Apache includes an SELinux profile, and we recommend that SELinux be deployed on the server.

## Installation

### Installation - RHEL 6/Apache 2.2

#### Before you begin

**Note:** For installation with the IBM HTTP Server on RedHat Enterprise Linux 6, see [Perform a manual installation with IBM HTTP Server](#) on page 289

Download and extract `pingaccess-agent-apache22-rhel6-<version>.zip`

**Note:** The Agent RPM has required dependencies that may be available via standard repositories. If these dependencies are not available in your Linux version, you can install them using the included

libpvm-5\_2-0-5.2.122-32.1.x86\_64.rpm, libsodium18-1.0.11-1.1.x86\_64.rpm, and libzmq5-4.3.1-23.6.x86\_64.rpm packages.

### About this task

To install the PingAccess Agent for Apache, perform the following steps:

#### Steps

1. In the PingAccess Console, go to the **Agents** page.
2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
4. In RHEL, change to the `pingaccess-agent-apache22-rhel6/x86_64` directory.
5. As root, install the PingAccess Agent for Apache using the following command:

```
yum install pingaccess-agent-apache-*.rpm lib*.rpm
```

6. Copy the `<agentname>_agent.properties` file to `/etc/httpd/conf.d/agent.properties`.
7. As root, restart the Apache service using the following command:

```
service httpd restart
```

### Manual Installation - RHEL 6/Apache 2.2

#### Before you begin

This procedure makes the following assumptions:

- The installation is being performed in a custom Apache instance run by a non-root user.
  - The Apache installation is assumed to be installed at `$APACHE`. In the steps in this procedure, modify the paths specified based on where your Apache installation and configuration files are located.
  - You have downloaded an `agent.properties` file. If you have not done so, you can do so using these steps:
1. In the PingAccess Console, navigate to the Sites & Agents page.
  2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
  3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.

#### About this task

Use the following procedure to manually install the PingAccess Agent for Apache when Apache is installed in a non-standard way:

#### Steps

1. Install the following required dependencies from the RedHat Official Repositories:

```
libcurl.x86_64
pcre.x86_64
```

2. Copy the RPMs from the zip distribution into a directory called `pkgroot` and unpack them using the following commands:

```
mkdir pkgroot
```

```
cp *.rpm pkgroot/
cd pkgroot
```

- Copy the extracted files to the appropriate places with the following commands:

```
cp etc/httpd/conf.d/paa.conf $APACHE/conf
cp -av usr/lib64/*.so* $APACHE/modules
cp usr/lib64/httpd/modules/*.so $APACHE/modules
```

- Add the following directive to the Apache configuration file (`$APACHE/conf/httpd.conf`) to include the PingAccess Agent for Apache module configuration:

```
Include conf/paa.conf
```

- Edit the `paa.conf` file and make the following changes:

- Add the following lines before the `LoadModule` directive:

```
LoadFile modules/libpgm-5.2.so.0
LoadFile modules/libsodium.so.18
LoadFile modules/libzmq.so.5
```

- Change all occurrences of `conf.d` to `conf`.

- Copy your downloaded `<hostname>_agent.properties` to `$APACHE/conf/agent.properties`.

- Execute the command `$APACHE/bin/apachectl restart` to restart Apache.

## Installation - RHEL 6/Apache 2.4

### Before you begin

This procedure makes the following assumptions:

- The Apache configuration directory is: `$APACHE_ROOT/conf`
- The Apache modules directory is: `$APACHE_ROOT/modules`

**Note:** The Agent RPM has required dependencies that may be available via standard repositories. If these dependencies are not available in your Linux version, you can install them using the included `libpgm-5_2-0-5.2.122-32.1.x86_64.rpm`, `libsodium18-1.0.11-1.1.x86_64.rpm`, and `libzmq5-4.3.1-23.6.x86_64.rpm` packages.

### About this task

#### Steps

- In the PingAccess Console, go to the **Agents** page.
- Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
- In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
- In RHEL, download and extract `pingaccess-agent-apache24-rhel6-<version>.zip`.
- Navigate to the `pingaccess-agent-apache24-rhel6` directory.
- Edit the included `paa.conf` to modify the values for Apache's configuration and module directories.
- Install the dependencies:

```
yum install ./x86_64/openpgm*.rpm ./x86_64/zeromq3*.rpm
```

- As root, copy the PingAccess Agent for Apache files to the appropriate places:

```
cp ./x86_64/mod_paa.so $APACHE_ROOT/modules
```

```
cp paa.conf $APACHE_ROOT/conf
```

**Note:** By default, Apache on RHEL will automatically include all .conf files contained within \$APACHE\_ROOT/conf (using the IncludeOptional directive). If this has been disabled, add the following to Apache's httpd.conf:

```
Include conf/paa.conf
```

9. Copy the <agentname>\_agent.properties file to \$APACHE\_ROOT/conf/agent.properties

10. As root, restart the Apache service using the following command:

```
$APACHE_ROOT/bin/apachectl restart
```

## Manual Installation - RHEL 6/Apache 2.4

### Before you begin

This procedure makes the following assumptions:

- You are installing the Agent in a custom Apache instance run by a non-root user.
- You can modify files and directories created by the Apache installer. If you installed Apache using yum, this procedure requires root access.
- The Apache installation is installed at \$APACHE. In the steps in this procedure, modify the paths specified based on where your Apache installation and configuration files are located.
- You have downloaded an agent.properties file. If you have not done so, you can do so using these steps:
  1. In the PingAccess Console, navigate to the **Sites & Agents** page.
  2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
  3. In the shared secret, click the download icon to download the configuration. The configuration file will be named <agentname>\_agent.properties.

### About this task

Use the following procedure to manually install the PingAccess Agent for Apache when Apache is installed in a non-standard way:

### Steps

1. Install the following required dependencies from the RedHat Official Repositories:

```
libcurl.x86_64
pcre.x86_64
```

2. Copy the Agent installation bundle to the target system and unpack it.
3. Change to the directory where you unpacked the Agent installation files.
4. Copy the extracted files to the appropriate places with the following commands:

```
cp paa.conf $APACHE/conf/
cd x86_64
cp mod_paa.so $APACHE/modules/
cp -av usr/lib64/*.so* $APACHE/modules/
```

5. Add the following directive to the Apache configuration file (\$APACHE/conf/httpd.conf) to include the PingAccess Agent for Apache module configuration:

```
Include conf/paa.conf
```

6. Edit the \$APACHE/conf/paa.conf file and make the following changes:

a) Add the following lines before the `LoadModule` directive:

```
LoadFile modules/libpgm-5.2.so.0
LoadFile modules/libsodium.so.18
LoadFile modules/libzmq.so.5
```

b) Change all occurrences of `conf.d` to `conf`.

7. Copy your downloaded `<agentname>_agent.properties` to `$APACHE/conf/agent.properties`.
8. Execute the command `$APACHE/bin/apachectl restart` to restart Apache.

## Installation - RHEL 7/Apache 2.2

### Before you begin

This procedure makes the following assumptions:

- The Apache configuration directory is: `$APACHE_ROOT/conf`
- The Apache modules directory is: `$APACHE_ROOT/modules`

**Note:** The Agent RPM has required dependencies that may be available via standard repositories. If these dependencies are not available in your Linux version, you can install them using the included `libpgm-5_2-0-5.2.122-32.1.x86_64.rpm`, `libsodium18-1.0.11-1.1.x86_64.rpm`, and `libzmq5-4.3.1-23.6.x86_64.rpm` packages.

### Steps

1. In the PingAccess Console, go to the **Agents** page.
2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
4. In RHEL, download and extract `pingaccess-agent-apache22-rhel7-<version>.zip`.
5. Navigate to the `pingaccess-agent-apache22-rhel7` directory.
6. Edit the included `paa.conf` to modify the values for Apache's configuration and module directories.
7. Install the dependencies:

```
yum install ./x86_64/openpgm*.rpm ./x86_64/zeromq3*.rpm
```

8. As root, copy the PingAccess Agent for Apache files to the appropriate places:

```
cp ./x86_64/mod_paa.so $APACHE_ROOT/modules
```

```
cp paa.conf $APACHE_ROOT/conf
```

**Note:** By default, Apache on RHEL will automatically include all `.conf` files contained within `$APACHE_ROOT/conf` (using the `IncludeOptional` directive). If this has been disabled, add the following to Apache's `httpd.conf`:

```
Include conf/paa.conf
```

9. Copy the `<agentname>_agent.properties` file to `$APACHE_ROOT/conf/agent.properties`
10. As root, restart the Apache service using the following command:

```
$APACHE_ROOT/bin/apachectl restart
```

## Manual Installation - RHEL 7/Apache 2.2

### Before you begin

This procedure makes the following assumptions:

- You are installing the Agent in a custom Apache instance run by a non-root user.
- You can modify files and directories created by the Apache installer. If you installed Apache using yum, this procedure requires root access.
- The Apache installation is assumed to be installed at `$APACHE`. In the steps in this procedure, modify the paths specified based on where your Apache installation and configuration files are located.
- You have downloaded an `agent.properties` file. If you have not done so, you can do so using these steps:
  1. In the PingAccess Console, navigate to the **Sites & Agents** page.
  2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
  3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.

### About this task

Use the following procedure to manually install the PingAccess Agent for Apache when Apache is installed in a non-standard way:

### Steps

1. Install the following required dependencies from the RedHat Official Repositories:

```
libcurl.x86_64
pcre.x86_64
```

2. Copy the Agent installation bundle to the target system and unpack it.
3. Change to the directory where you unpacked the Agent installation files.
4. Copy the extracted files to the appropriate places with the following commands:

```
cp paa.conf $APACHE/conf/
cd x86_64
cp mod_paa.so $APACHE/modules/
cp -av usr/lib64/*.so* $APACHE/modules/
```

5. Add the following directive to the Apache configuration file (`$APACHE/conf/httpd.conf`) to include the PingAccess Agent for Apache module configuration:

```
Include conf/paa.conf
```

6. Edit the `$APACHE/conf/paa.conf` file and make the following changes:
  - a) Add the following lines before the `LoadModule` directive:

```
LoadFile modules/libpgm-5.2.so.0
LoadFile modules/libsodium.so.18
LoadFile modules/libzmq.so.5
```

- b) Change all occurrences of `conf.d` to `conf`.
7. Copy your downloaded `<hostname>_agent.properties` to `$APACHE/conf/agent.properties`.
  8. Execute the command `$APACHE/bin/apachectl restart` to restart Apache.

### Installation - RHEL 7/Apache 2.4

#### Before you begin

**Note:** For installation with the IBM HTTP Server on RedHat Enterprise Linux 7, see [Perform a manual installation with IBM HTTP Server](#) on page 289

Download and extract `pingaccess-agent-apache24-rhel7-<version>.zip`

**Note:** The Agent RPM has required dependencies that may be available via standard repositories. If these dependencies are not available in your Linux version, you can install them using the included `libpgm-5_2-0-5.2.122-32.1.x86_64.rpm`, `libsodium18-1.0.11-1.1.x86_64.rpm`, and `libzmq5-4.3.1-23.6.x86_64.rpm` packages.

### About this task

To install the PingAccess Agent for Apache, perform the following steps:

#### Steps

1. In the PingAccess Console, go to the **Agents** page.
2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
4. in RHEL, change to the `pingaccess-agent-apache24-rhel7/x86_64` directory.
5. As root, install the PingAccess Agent for Apache using the following command:

```
yum install pingaccess-agent-apache-*.rpm lib*.rpm
```

6. Copy the `<agentname>_agent.properties` file to `/etc/httpd/conf.d/agent.properties`.
7. As root, restart the Apache service using the following command:

```
systemctl restart httpd.service
```

### Manual Installation - RHEL 7/Apache 2.4

#### Before you begin

This procedure makes the following assumptions:

- The installation is being performed in a custom Apache instance run by a non-root user.
- The Apache installation is assumed to be installed at `$APACHE`. In the steps in this procedure, modify the paths specified based on where your Apache installation and configuration files are located.
- You have downloaded an `agent.properties` file. If you have not done so, you can do so using these steps:

1. In the PingAccess Console, navigate to the Sites & Agents page.
2. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
3. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.

#### About this task

Use the following procedure to manually install the PingAccess Agent for Apache when Apache is installed in a non-standard way:

#### Steps

1. Install the following required dependencies from the RedHat Official Repositories:

```
libcurl.x86_64
pcre.x86_64
```

- Copy the RPMs from the zip distribution into a directory called `pkgroot` and unpack them using the following commands:

```
mkdir pkgroot
cp *.rpm pkgroot/
cd pkgroot
```

- Copy the extracted files to the appropriate places with the following commands:

```
cp etc/httpd/conf.modules.d/10-paa.conf $APACHE/conf
cp -av usr/lib64/*.so* $APACHE/modules
cp usr/lib64/httpd/modules/*.so $APACHE/modules
```

- Add the following directive to the Apache configuration file (`$APACHE/conf/httpd.conf`) to include the PingAccess Agent for Apache module configuration:

```
Include conf/10-paa.conf
```

- Edit the `10-paa.conf` file and make the following changes:

- Add the following lines before the `LoadModule` directive:

```
LoadFile modules/libpgm-5.2.so.0
LoadFile modules/libsodium.so.18
LoadFile modules/libzmq.so.5
```

- Change all occurrences of `conf.d` to `conf`.

- Copy your downloaded `<hostname>_agent.properties` to `$APACHE/conf/agent.properties`.

- Execute the command `$APACHE/bin/apachectl restart` to restart Apache.

## Perform a manual installation with IBM HTTP Server

### Before you begin

This procedure makes the following assumptions:

- The IBM HTTP Server has been installed and configured following IBM's documentation.
- The environment is running on RedHat Enterprise Linux 6 or RedHat Enterprise Linux 7.
- You have downloaded the appropriate `pingaccess-agent-apache22-*.zip` distribution file and have unzipped it.
- You have configured an agent in PingAccess, and have downloaded the `<agentname>_agent.properties` file.
- `apachectl` for the running IBM HTTP Server instance is in the path.
- The Apache installation is assumed to live at `$APACHE`. In the steps in this procedure, modify the paths specified based on where your Apache installation and configuration files are located.
- You have installed `libcurl` and `PCRE` or verified that they are installed. To install these packages, use this command:

```
yum install libcurl pcre
```

### About this task

Use the following steps to install the PingAccess Agent for Apache when using the IBM HTTP Server:

### Steps

- Change to the `pingaccess-agent-apache22-rhel<n>-<version>/<arch>/` directory.

**Note:** Valid values for `<arch>` are `x86` for 32-bit and `x86_64` for 64-bit. 32-bit binaries are only available and supported on RHEL 7.

For example: `cd pingaccess-agent-apache22-rhel7-1.2.0/x86/`

2. Extract the package RPMs with the command:

```
mkdir pkgroot
cp *.rpm pkgroot/
cd pkgroot
for r in *.rpm; do rpm2cpio $r | cpio -idmv; done
```

3. Execute the following command to copy the libraries to the appropriate Apache directories:

- For RedHat Enterprise Linux 6 and 7 (x86\_64):

```
cp -av usr/lib64/*.so* $APACHE/modules
```

- For RedHat Enterprise Linux 7 (x86):

```
cp -av usr/lib/*.so* $APACHE/modules
```

4. Copy `mod_paa.so` into the Apache modules directory:

- For RedHat Enterprise Linux 6:

```
cp -av usr/lib64/httpd/modules/mod_paa.so $APACHE/modules
```

- For RedHat Enterprise Linux 7:

```
cp -av ../mod_paa.so $APACHE/modules
```

5. Copy `paa.conf` to the Apache configuration directory:

- For RedHat Enterprise Linux 6:

```
cp -av etc/httpd/conf.d/paa.conf $APACHE/conf
```

- For RedHat Enterprise Linux 7:

```
cp -av ../paa.conf $APACHE/conf
```

6. Edit `paa.conf` and add the following lines before the `LoadModule` directive:

- For RedHat Enterprise Linux 6:

```
LoadFile modules/libpgm-5.1.so.0
LoadFile modules/libzmq.so.3
```

- For RedHat Enterprise Linux 7:

```
LoadFile modules/libpgm-5.2.so.0
LoadFile modules/libzmq.so.3
```

7. In `paa.conf`, update the values for `PaaPropertyFiles` and `PaaCertificateDir` to point to your Apache `conf` directory.

8. Add the following directive to the Apache configuration file (`$APACHE/conf/httpd.conf`) to include the PingAccess Agent for Apache module configuration:

```
Include conf/paa.conf
```

9. Copy the `<agentname>_agent.properties` file to `$APACHE/conf/agent.properties`.

10. Restart the Apache service by running `apachectl restart`.

## Uninstall

You can remove the PingAccess Agent from an RHEL system.

### About this task

If you installed the Ping Access Agent using the standard installation process, you can uninstall it with this command:

```
sudo yum remove pingaccess-agent-rhel.x86_64
```

If you installed the Ping Access Agent manually with an IBM HTTP Server, you can uninstall it with this procedure:

### Steps

1. Remove the `$APACHE/conf/agent.properties` file:

```
rm $APACHE/conf/agent.properties
```

2. Remove the following directive from the Apache configuration file (`$APACHE/conf/httpd.conf`):

```
Include conf/paa.conf
```

3. Remove `paa.conf` from the `$APACHE/modules` directory:

```
rm $APACHE/modules/paa.conf
```

4. Remove all `.so` files from the `$APACHE/modules` directory:

```
rm $APACHE/modules/*.so*
```

5. Restart the Apache service by running `apachectl restart`.

## Configuration

The agent configuration is managed through the `paa.conf` and `agent.properties` configuration files.

The `/etc/httpd/conf.d/paa.conf` file contains these configuration options:

Parameter	Definition	Default Value
PaaCertificateDir	String value containing the path to the certificates extracted from the <code>.properties</code> files.	conf.d

Parameter	Definition	Default Value
PaaEnabled	<p>Determines whether the agent is enabled or disabled for a specific server configuration. Valid values: on/off</p> <p>This value can be set globally; set for individual virtual hosts, directories, locations, or files; or both. The most specific value is used.</p> <p><b>Note:</b> If you disable the PaaEnabled parameter globally, ensure that the PaaEnabled directive is set to on for the PingAccess reserved application context root. This is /pa by default.</p> <p>For example, adding this text to an included configuration file enables PingAccess for the /pa context root and for the /var/www/html/one directory:</p> <pre data-bbox="574 821 1045 1104" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Location /pa&gt;     PaaEnabled on   &lt;/Location&gt;   &lt;Directory "/var/www/html/one"&gt;     PaaEnabled on   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre> <p>Adding this text to an included configuration file disables PingAccess for all content in the /var/www/html/two directory except for files named page2.html.</p> <pre data-bbox="574 1297 1045 1581" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Directory "/var/www/html/two"&gt;     PaaEnabled off     &lt;Files "page2.html"&gt;       PaaEnabled on     &lt;/Files&gt;   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre>	on
PaaPropertyFiles	List of .properties files which store configuration data used to connect the agent to the PingAccess engine nodes the agent will communicate with.	conf.d/agent.properties

Parameter	Definition	Default Value
PaaEnabledNoteName	<p>An optional parameter which defines a note name. If a request includes a note with this name and a value of on or off, this value overrides the PaaEnabled setting for that request.</p> <p>If you want to use this feature, you must deploy a custom module to include this note with the correct value.</p>	paa-enabled-note

The configured `agent.properties` files can contain the following parameters:

Parameter	Definition	Default Value
agent.engine.configuration.scheme	The URI scheme used to connect to the engine node. Valid values are http and https.	https
agent.engine.configuration.host	The PingAccess hostname.	The value in the Agent Node's PingAccess Host field.
agent.engine.configuration.port	The port the agent connects to on the PingAccess host. This value is defined in the PingAccess <code>run.properties</code> file.	Defined in the PingAccess Admin UI
agent.engine.configuration.username	The unique agent name that identifies the agent in PingAccess.	Defined in the PingAccess Admin UI
agent.engine.configuration.shared.secret	The password used to authenticate the agent to the engine.	Defined in the PingAccess Admin UI
agent.engine.configuration.bootstrap.truststore	<p>The base64-encoded public certificate used to establish HTTPS trust by the agent to the PingAccess engine.</p> <p><b>Note:</b> If you are having difficulty connecting an agent to the PingAccess engine, verify that the Agent Trusted Certificate has been configured correctly in <a href="#">Agent Management</a>.</p>	Generated by PingAccess
agent.engine.configuration.maxConnections	The number of connections a single web server worker process maintains to the PingAccess engine defined in the <code>agent.engine.configuration.host</code> parameter.	10
agent.engine.configuration.timeout	The maximum time (in milliseconds) a request to PingAccess can take from the agent. If this time is exceeded, the client will receive a generic 500 <code>Server Error</code> response.	30000

Parameter	Definition	Default Value
agent.engine.configuration.connectTimeout	The maximum time (in milliseconds) the agent can take to connect to the PingAccess engine. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.cache.missInitialTimeout	The maximum time (in milliseconds) a web server worker process waits for a response to a policy cache request sent to other web server worker processes.	5
agent.cache.broker.publisherPort	The network port web server processes use to publish policy cache requests to other web server worker processes. This port is bound to the localhost network only.	3031
agent.cache.broker.subscriberPort	The network port web server processes use to receive policy cache requests from other web server worker processes. This port is bound to the localhost network only.	3032
agent.cache.maxTokens	The maximum number of tokens stored in the policy cache for a single web server worker process. A value of 0 means there is no maximum.	0
agent.cache.disabled	<p>Determines whether caching of policy decisions is enabled or disabled. A value of 1 disables caching, forcing the agent to communicate with the PingAccess host any time a policy decision needs to be made.</p> <p> <b>Warning:</b> Disabling caching has a significant impact on the scalability of the PingAccess Policy servers, as every rule evaluation is processed by the Policy Server. This option should only be used as a last resort because of the performance penalty.</p>	0

Changes to the `agent.properties` file require a restart of the web server.

**Tip:** See the [Performance Tuning Guide](#) for a discussion on improving agent performance.

## Adding trust for an anchor certificate

You can add trust for an anchor certificate.

### Steps

1. Use the `certutil` command to add certificates to the `cert9.db` file. For example:

```
certutil -L -d sql: /etc/pki/nssdb
```

2. Clear the `agent.engine.configuration.bootstrap.truststore` property in `agent.properties` to have the agent fallback to the system truststore (`/etc/pki/nssdb` in the example).

### Log Configuration

The PingAccess Agent for Apache writes its information to the standard Apache error log, defined in the Apache configuration with the `ErrorLog` configuration directive. All information logged by the PingAccess Agent is prefaced with the string `[paa]`. PingAccess Agent monitoring and performance information is prefaced with the string `[paa-monitoring]`, and contains information about how long the PingAccess Agent took to fill a cache request and how long the total policy decision took.

The `LogLevel` used by the PingAccess Agent module is taken from the top-level `httpd.conf` configuration.

## Troubleshooting

The following table lists some potential problems and resolutions you might encounter with the PingAccess Agent for RHEL.

Issue	Resolution
Agent receives an unknown protocol error when attempting to contact the administrative node	<p>This can indicate that the operating system is using sha1 for encryption. This protocol is no longer supported by default in PingAccess.</p> <p>We recommend switching to sha256. If you cannot switch to sha256, you can re-enable sha1:</p> <ol style="list-style-type: none"> <li>1. Open the <code>run.properties</code> file.</li> <li>2. Add TLSv1 to the protocol list. For example: <pre>tls.default.protocols=<b>TLSv1</b>, TLSv1.1, TLSv1.2</pre> </li> <li>3. Add the SHA entries to the cipher suites list. For example: <pre>tls.default.cipherSuites =   TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256, \   TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256, \   TLS_RSA_WITH_AES_128_GCM_SHA256, \   TLS_RSA_WITH_AES_128_CBC_SHA256, \   TLS_DHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_EMPTY_RENEGOTIATION_INFO_SCSV, \ <b>TLS_RSA_WITH_AES_128_CBC_SHA, \   TLS_DHE_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA</b></pre> </li> </ol>

## Release Notes

### Version History

- **Version 1.4** – June 2019  
Agent SDK for C version 1.2.0
  - The PAAEnabled directive can now be used inside a directory or location container
  - Added ability to set policy caching mechanism using a property in the `agent.properties` file
  - Added ability to enable or disable agent processing for a request based on a note field
  - Fixed a potential security issue
- **Version 1.3.2** – November 2018
  - Fixed a potential security issue
- **Version 1.3** – February 2017
  - Added support for Apache 2.4 on RHEL 6
  - The Agent can now be disabled for specific hosts using the new configuration option: `PaaEnabled`
- **Version 1.2** – May 2016
  - Added support for IBM HTTP Server
- **Version 1.1** – December 2014
  - Added Support for Apache 2.4 on RedHat Enterprise Linux 7
  - Corrected a potential security issue related to caching (SECBL007). This security bulletin is available in the Ping Identity Support Portal (<https://ping.force.com/support/>).
- **Version 1.0** – July 2014
  - Initial Release

## PingAccess Agent for Apache (SLES)

---

### Introduction

The PingAccess Agent for Apache is an Apache module that intercepts requests to the web server's protected resources and evaluates applicable access control policies. These policies are evaluated by either accessing a locally cached policy decision or by querying the PingAccess engine node.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

Within the PingAccess Administration Console, agent nodes are configured with information that allows a PingAccess Agent to connect to the engine node to retrieve information about access control policies for resources within that agent's control. An agent configuration has a one-to-many relationship with PingAccess agents, allowing a single agent configuration bootstrap file to be used on multiple web servers within a server farm.

**Tip:** An agent node is a shared configuration used by one or more agents, rather than a specific agent instance.

## System Requirements

The PingAccess Agent for Apache is supported on the following platforms:

- Apache HTTP Server 2.2 running on SUSE Linux Enterprise Server 11 SP4 (x86\_64)
- Apache HTTP Server 2.4 running on SUSE Linux Enterprise Server 12 SP2 (x86\_64)

As with any system that is reachable from the Internet, the server should be properly hardened. The PingAccess Agent for Apache includes an SELinux profile, and we recommend that SELinux be deployed on the server.

## Installation

### Before you begin

This procedure makes the following assumptions:

- The Apache configuration directory is: `/etc/apache2/conf.d`
- The Apache modules directory is: `/usr/lib64/apache2`

For custom installations:

- Modify the configuration and module paths below as needed.
- Edit the included `paa.conf` to modify the values for Apache's configuration and module directories.

**To install the PingAccess Agent for Apache, perform the following steps:**

## Steps

1. Download and extract `pingaccess-agent-apache<version>.zip`.
2. Navigate to the `pingaccess-agent-apache<version>` directory.
3. If you are installing on SLES 12, import the gpg key:

```
rpm --import https://download.opensuse.org/repositories/network:/messaging:/zeromq:/release-stable/SLE_12_SP4/repodata/repomd.xml.key
```

4. Install the dependencies:

```
zypper in ./x86_64/lib*.rpm
```

5. As root, copy the PingAccess Agent for Apache files to the appropriate places:

```
cp ./x86_64/mod_paa.so /usr/lib64/apache2
```

```
cp paa.conf /etc/apache2/conf.d
```

**Note:** By default, Apache on SLES will automatically include all `.conf` files contained within `conf.d` (using the `IncludeOptional` directive). If this has been disabled, add the following to Apache's `httpd.conf`:

```
Include /etc/apache2/conf.d/paa.conf
```

6. In the PingAccess Console, go to the **Agents** page.
7. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
8. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
9. Copy the `<agentname>_agent.properties` file to `/etc/apache2/conf.d/agent.properties`
10. As root, restart the Apache service using one of the following commands:

```
rcapache2 restart
```

```
$APACHE_ROOT/bin/apachectl restart
```

## Uninstall

You can remove the PingAccess Agent from a SUSE Linux system.

## Steps

Run this command:

```
sudo zypper rm pingaccess-agent-suse.x86_64
```

## Configuration

The agent configuration is managed through the `paa.conf` and `agent.properties` configuration files.

The `/etc/httpd/conf.d/paa.conf` file contains these configuration options:

Parameter	Definition	Default Value
PaaCertificateDir	String value containing the path to the certificates extracted from the <code>.properties</code> files.	<code>conf.d</code>

Parameter	Definition	Default Value
PaaEnabled	<p>Determines whether the agent is enabled or disabled for a specific server configuration. Valid values: on/off</p> <p>This value can be set globally; set for individual virtual hosts, directories, locations, or files; or both. The most specific value is used.</p> <p><b>Note:</b> If you disable the PaaEnabled parameter globally, ensure that the PaaEnabled directive is set to on for the PingAccess reserved application context root. This is <code>/pa</code> by default.</p> <p>For example, adding this text to an included configuration file enables PingAccess for the <code>/pa</code> context root and for the <code>/var/www/html/one</code> directory:</p> <pre data-bbox="646 947 1040 1234" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Location /pa&gt;     PaaEnabled on   &lt;/Location&gt;   &lt;Directory "/var/www/html/one"&gt;     PaaEnabled on   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre> <p>Adding this text to an included configuration file disables PingAccess for all content in the <code>/var/www/html/two</code> directory except for files named <code>page2.html</code>.</p> <pre data-bbox="646 1455 1040 1795" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Directory "/var/www/html/two"&gt;     PaaEnabled off     &lt;Files       "page2.html"&gt;         PaaEnabled       on     &lt;/Files&gt;   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre>	on

Parameter	Definition	Default Value
PaaPropertyFiles	List of .properties files which store configuration data used to connect the agent to the PingAccess engine nodes the agent will communicate with.	conf.d/agent.properties
PaaEnabledNoteName	An optional parameter which defines a note name. If a request includes a note with this name and a value of on or off, this value overrides the PaaEnabled setting for that request.  If you want to use this feature, you must deploy a custom module to include this note with the correct value.	paa-enabled-note

**Note:** It is not necessary to make any changes to paa.conf if the steps in the [Installation](#) section were followed.

The configured `agent.properties` files can contain the following parameters:

Parameter	Definition	Default Value
agent.engine.configuration.scheme	The URI scheme used to connect to the engine node. Valid values are http and https.	https
agent.engine.configuration.host	The PingAccess hostname.	The value in the Agent Node's PingAccess Host field.
agent.engine.configuration.port	The port the agent connects to on the PingAccess host. This value is defined in the PingAccess <code>run.properties</code> file.	Defined in the PingAccess Admin UI
agent.engine.configuration.username	The unique agent name that identifies the agent in PingAccess.	Defined in the PingAccess Admin UI
agent.engine.configuration.shared.secret	The password used to authenticate the agent to the engine.	Defined in the PingAccess Admin UI
agent.engine.configuration.bootstrap	The base64-encoded public certificate used to establish HTTPS trust by the agent to the PingAccess engine.  <b>Note:</b> If you are having difficulty connecting an agent to the PingAccess engine, verify that the Agent Trusted Certificate has been configured correctly in <a href="#">Agent Management</a> .	Generated by PingAccess

Parameter	Definition	Default Value
agent.engine.configuration.maxConnections	The number of connections a single web server worker process maintains to the PingAccess engine defined in the agent.engine.configuration.host parameter.	10
agent.engine.configuration.timeout	The maximum time (in milliseconds) a request to PingAccess can take from the agent. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.engine.configuration.connectTimeout	The maximum time (in milliseconds) the agent can take to connect to the PingAccess engine. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.cache.missInitialTimeout	The maximum time (in milliseconds) a web server worker process waits for a response to a policy cache request sent to other web server worker processes.	5
agent.cache.broker.publisherPort	The network port web server processes use to publish policy cache requests to other web server worker processes. This port is bound to the localhost network only.	3031
agent.cache.broker.subscriberPort	The network port web server processes use to receive policy cache requests from other web server worker processes. This port is bound to the localhost network only.	3032
agent.cache.maxTokens	The maximum number of tokens stored in the policy cache for a single web server worker process. A value of 0 means there is no maximum.	0

Parameter	Definition	Default Value
agent.cache.disabled	<p>Determines whether caching of policy decisions is enabled or disabled. A value of 1 disables caching, forcing the agent to communicate with the PingAccess host any time a policy decision needs to be made.</p> <p> <b>Warning:</b> Disabling caching has a significant impact on the scalability of the PingAccess Policy servers, as every rule evaluation is processed by the Policy Server. This option should only be used as a last resort because of the performance penalty.</p>	0

Changes to the `agent.properties` file require a restart of the web server.

**Tip:** See the [Performance Tuning Guide](#) for a discussion on improving agent performance.

### Adding trust for an anchor certificate

You can add trust for an anchor certificate.

#### Steps

1. Use the `certutil` command to add certificates to the `cert9.db` file. For example:

```
certutil -L -d sql: /etc/pki/nssdb
```

2. Clear the `agent.engine.configuration.bootstrap.truststore` property in `agent.properties` to have the agent fallback to the system truststore (`/etc/pki/nssdb` in the example).

### Log Configuration

The PingAccess Agent for Apache writes its information to the standard Apache error log, defined in the Apache configuration with the `ErrorLog` configuration directive. All information logged by the PingAccess Agent is prefaced with the string `[paa]`. PingAccess Agent monitoring and performance information is prefaced with the string `[paa-monitoring]`, and contains information about how long the PingAccess Agent took to fill a cache request and how long the total policy decision took.

The `LogLevel` used by the PingAccess Agent module is taken from the top-level `httpd.conf` configuration.

## Troubleshooting

The table below lists some potential problems and resolutions you may encounter with the PingAccess Agent for SLES.

Issue	Resolution
<p>Agent receives an unknown protocol error when attempting to contact the administrative node</p>	<p>This can indicate that the operating system is using sha1 for encryption. This protocol is no longer supported by default in PingAccess.</p> <p>We recommend switching to sha256. If you cannot switch to sha256, you can re-enable sha1:</p> <ol style="list-style-type: none"> <li>1. Open the <code>run.properties</code> file.</li> <li>2. Add TLSv1 to the protocol list. For example: <pre data-bbox="602 464 1464 520">tls.default.protocols=<b>TLSv1</b>, TLSv1.1, TLSv1.2</pre> </li> <li>3. Add the SHA entries to the cipher suites list. For example: <pre data-bbox="602 575 1464 1045">tls.default.cipherSuites =   TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256, \   TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256, \   TLS_RSA_WITH_AES_128_GCM_SHA256, \   TLS_RSA_WITH_AES_128_CBC_SHA256, \   TLS_DHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_EMPTY_RENEGOTIATION_INFO_SCSV, \ <b>TLS_RSA_WITH_AES_128_CBC_SHA, \   TLS_DHE_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA</b></pre> </li> </ol>

## Release Notes

### Version History

- **Version 1.4** – June 2019
  - Agent SDK for C version 1.2.0
  - The PAAEnabled directive can now be used inside a directory or location container
  - Added ability to set policy caching mechanism using a property in the `agent.properties` file
  - Added ability to enable or disable agent processing for a request based on a note field
  - Fixed a potential security issue
- **Version 1.3.2** – November 2018
  - Fixed a potential security issue
- **Version 1.3** – March 2017
  - Initial release for Apache 2.2 on SLES 11 and Apache 2.4 on SLES 12
  - Note:** Version is aligned with PingAccess Agent for Apache (RHEL)

## PingAccess Agent for Apache (Windows)

### Introduction

The PingAccess Agent for Apache is an Apache module that intercepts requests to the web server's protected resources and evaluates applicable access control policies. These policies are evaluated by either accessing a locally cached policy decision or by querying the PingAccess engine node.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

Within the PingAccess Administration Console, agent nodes are configured with information that allows a PingAccess Agent to connect to the engine node to retrieve information about access control policies for resources within that agent's control. An agent configuration has a one-to-many relationship with PingAccess agents, allowing a single agent configuration bootstrap file to be used on multiple web servers within a server farm.

**Tip:** An agent node is a shared configuration used by one or more agents, rather than a specific agent instance.

## System requirements

The PingAccess Agent for Apache is supported on the following platforms:

- Apache HTTP Server 2.4 64-bit running on Microsoft Windows Server 2012 R2 Datacenter, VC14 or higher
- Apache HTTP Server 2.4 64-bit running on Microsoft Windows Server 2016, VC14 or higher

As with any system that is reachable from the Internet, the server should be properly hardened.

## Installation

### Before you begin

This procedure makes the following assumptions:

- The Apache configuration directory is: `C:/apache24/conf`
- The Apache modules directory is: `C:/apache24/modules`

For custom installations:

- Modify the configuration and module paths below as needed.
- Edit the included `paa.conf` to modify the values for Apache's configuration and module directories.

To install the PingAccess Agent for Apache, perform the following steps:

### Steps

1. Download and extract `pingaccess-agent-apache<version>.zip`.

2. Go to the `pingaccess-agent-apache<version>` directory.
3. Copy the `paa.conf` file into the Apache configuration directory.
4. Add the following to Apache's `httpd.conf` file:

```
Include conf/paa.conf
```

5. Copy the `paa` folder into the Apache modules directory.
6. In the PingAccess Console, go to the **Agents** page.
7. Edit a configured agent. If the agent has not yet been created, see the [PingAccess User Interface Reference Guide](#).
8. In the shared secret, click **Download** to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
9. On the Agent system, create the `C:/apache24/conf.d` folder if it does not exist.
10. Copy the `<agentname>_agent.properties` file to `C:/apache24/conf.d/agent.properties`.
11. Restart Apache.

## Uninstall

You can remove the PingAccess Agent from a Windows system.

### Steps

1. Remove the `C:/apache24/conf.d` folder and its contents.
2. Remove the `paa` folder from the Apache modules directory.
3. Remove the following from Apache's `httpd.conf` file:

```
Include conf/paa.conf
```

4. Remove the `paa.conf` file from the Apache configuration directory.
5. Remove the `pingaccess-agent-apache<version>` directory.
6. Remove the `pingaccess-agent-apache<version>.zip` file if it is present.
7. Restart Apache.

## Configuration

The agent configuration is managed through the `paa.conf` and `agent.properties` configuration files.

The `C:/Apache24/conf/paa.conf` file contains these configuration options:

Parameter	Definition	Default Value
PaaCertificateDir	String value containing the path to the certificates extracted from the <code>.properties</code> files.	<code>conf.d</code>

Parameter	Definition	Default Value
PaaEnabled	<p data-bbox="641 216 1034 338">Determines whether the agent is enabled or disabled for a specific server configuration. Valid values: on/off</p> <p data-bbox="641 359 1016 512">This value can be set globally; set for individual virtual hosts, directories, locations, or files; or both. The most specific value is used.</p> <p data-bbox="641 533 1024 751"><b>Note:</b> If you disable the PaaEnabled parameter globally, ensure that the PaaEnabled directive is set to on for the PingAccess reserved application context root. This is <code>/pa</code> by default.</p> <p data-bbox="641 772 1019 926">For example, adding this text to an included configuration file enables PingAccess for the <code>/pa</code> context root and for the <code>/var/www/html/one</code> directory:</p> <pre data-bbox="656 961 997 1213" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Location /pa&gt;     PaaEnabled on   &lt;/Location&gt;   &lt;Directory "/var/www/html/one"&gt;     PaaEnabled on   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre> <p data-bbox="641 1247 1013 1436">Adding this text to an included configuration file disables PingAccess for all content in the <code>/var/www/html/two</code> directory except for files named <code>page2.html</code>.</p> <pre data-bbox="656 1472 1008 1776" style="background-color: #f0f0f0; padding: 10px;"> &lt;VirtualHost *:81&gt;   &lt;Directory "/var/www/html/two"&gt;     PaaEnabled off     &lt;Files       "page2.html"&gt;       PaaEnabled     on     &lt;/Files&gt;   &lt;/Directory&gt; &lt;/VirtualHost&gt; </pre>	on

Parameter	Definition	Default Value
PaaPropertyFiles	List of <code>.properties</code> files that store configuration data used to connect the agent to the PingAccess engine nodes the agent will communicate with.	conf.d/agent.properties
PaaEnabledNoteName	An optional parameter which defines a note name. If a request includes a note with this name and a value of on or off, this value overrides the PaaEnabled setting for that request.  If you want to use this feature, you must deploy a custom module to include this note with the correct value.	paa-enabled-note

The configured `agent.properties` files can contain the following parameters:

Parameter	Definition	Default Value
agent.engine.configuration.scheme	The URI scheme used to connect to the engine node. Valid values are http and https.	https
agent.engine.configuration.host	The PingAccess hostname.	The value in the Agent Node's PingAccess Host field.
agent.engine.configuration.port	The port the agent connects to on the PingAccess host. This value is defined in the PingAccess <code>run.properties</code> file.	Defined in the PingAccess Admin UI
agent.engine.configuration.username	The unique agent name that identifies the agent in PingAccess.	Defined in the PingAccess Admin UI
agent.engine.configuration.shared.secret	The password used to authenticate the agent to the engine.	Defined in the PingAccess Admin UI
agent.engine.configuration.bootstrap.truststore	The base64-encoded public certificate used to establish HTTPS trust by the agent to the PingAccess engine.  <b>Note:</b> If you are having difficulty connecting an agent to the PingAccess engine, verify that the Agent Trusted Certificate has been configured correctly in <a href="#">Agent Management</a> .	Generated by PingAccess

Parameter	Definition	Default Value
agent.engine.configuration.maxConnections	The number of connections a single web server worker process maintains to the PingAccess engine defined in the agent.engine.configuration.host parameter.	10
agent.engine.configuration.timeout	The maximum time (in milliseconds) a request to PingAccess can take from the agent. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.engine.configuration.connectTimeout	The maximum time (in milliseconds) the agent can take to connect to the PingAccess engine. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.cache.missInitialTimeout	The maximum time (in milliseconds) a web server worker process waits for a response to a policy cache request sent to other web server worker processes.	5
agent.cache.broker.publisherPort	The network port web server processes use to publish policy cache requests to other web server worker processes. This port is bound to the localhost network only.	3031
agent.cache.broker.subscriberPort	The network port web server processes use to receive policy cache requests from other web server worker processes. This port is bound to the localhost network only.	3032
agent.cache.maxTokens	The maximum number of tokens stored in the policy cache for a single web server worker process. A value of 0 means there is no maximum.	0

Parameter	Definition	Default Value
agent.cache.disabled	<p>Determines whether caching of policy decisions is enabled or disabled. A value of 1 disables caching, forcing the agent to communicate with the PingAccess host any time a policy decision needs to be made.</p> <p> <b>Warning:</b> Disabling caching has a significant impact on the scalability of the PingAccess Policy servers, as every rule evaluation is processed by the Policy Server. This option should only be used as a last resort because of the performance penalty.</p>	0
agent.cache.type	<p>Controls the type of policy cache used by the agent. There are three valid values for this property:</p> <ul style="list-style-type: none"> <li>• AUTO - The AUTO cache type determines the appropriate cache to use based on the number of worker processes. If the number of worker processes is 1, or 16 or above, the agent uses the STANDALONE cache. If the number of worker processes is between 2 and 15, the agent uses the ZMQ cache.</li> <li>• STANDALONE - The STANDALONE cache type does not share policy cache entries across worker processes.</li> <li>• ZMQ - The ZMQ cache type allows the agent to share policy cache entries across all worker processes using ZeroMQ for inter-process communication.</li> </ul>	AUTO

Changes to the `agent.properties` file require a restart of the web server.

**Tip:** See the [Performance tuning guide](#) for a discussion on improving agent performance.

### Log configuration

The PingAccess Agent for Apache writes its information to the standard Apache error log, defined in the Apache configuration with the `ErrorLog` configuration directive. All information logged by the PingAccess

Agent is prefaced with the string `[paa]`. PingAccess Agent monitoring and performance information is prefaced with the string `[paa-monitoring]`, and contains information about how long the PingAccess Agent took to fill a cache request and how long the total policy decision took.

The LogLevel used by the PingAccess Agent module is taken from the top-level `httpd.conf` configuration.

## Release notes

### Version history

- **Version 1.4** – July 2019

Agent SDK for C version 1.2.0

- Initial release for Apache 2.4 on Windows

**Note:** Version is aligned with PingAccess Agent for Apache (RHEL).

## PingAccess Agent for IIS

### Introduction

The PingAccess Agent for IIS is a Microsoft Internet Information Services module that intercepts requests to the web server's protected resources and evaluates applicable access control policies. These policies are evaluated by either accessing a locally cached policy decision or by querying the PingAccess engine node.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.

5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

Within the PingAccess Administration Console, Agent Nodes are configured with information that allows a PingAccess Agent to connect to the engine node to retrieve information about access control policies for resources within that agent's control. An agent configuration has a one-to-many relationship with PingAccess agents, allowing a single agent configuration bootstrap file to be used on multiple web servers within a server farm.

**Note:** An Agent Node is a shared configuration used by one or more agents, rather than a specific agent instance.

**Tip:** It is possible that a problem with the PingAccess IIS agent configuration can cause all applications in an IIS application pool to become unreachable. To maximize availability of unprotected resources, place applications protected by the PingAccess agent in a separate pool.

## System Requirements

To install the PingAccess Agent for IIS, the following is required:

- Microsoft Internet Information Services (IIS) 7.0 running on Windows Server 2008
- Microsoft Internet Information Services (IIS) 7.5 running on Windows Server 2008 R2
- Microsoft Internet Information Services (IIS) 8.0 running on Windows Server 2012 Datacenter Edition
- Microsoft Internet Information Services (IIS) 8.5 running on Windows Server 2012 R2 Datacenter and Standard Edition
- Microsoft Internet Information Services (IIS) 10.0 running on Windows Server 2016

**Note:** Only 64-bit Windows platforms and versions of IIS are supported. 32-bit compatibility mode for IIS is not supported by the PingAccess Agent for IIS.

All of the other dependencies required for the agent are included in the .msi installation package.

As with any system that is reachable from the Internet, the server should be properly hardened.

## Installation

### Before you begin

Prior to starting the installation of the PingAccess Agent for IIS, shut down any running programs, including the Windows Event Viewer. Running applications may cause the installation to fail.

**Important:** If the system is running application pools in 32-bit compatibility mode, review the [Troubleshooting](#) for information about preventing a known issue.

### About this task

To install the PingAccess Agent for IIS, perform the following steps:

### Steps

1. Unzip the PingAccess Agent for IIS zip file.

**Note:** The installer cannot be run from inside the zip file; it must first be extracted.

2. Run the `pingaccess-agent-iis.msi` installer.
3. In the PingAccess Console, go to the **Agents** page.
4. Edit a configured agent. If the agent has not yet been created, follow the procedure in the [PingAccess User Interface Reference Guide](#).
5. In the shared secret, click the download icon to download the configuration. The configuration file will be named `<agentname>_agent.properties`.
6. Copy the `<agentname>_agent.properties` file to `C:\Program Files\Ping Identity\PingAccess Agent for IIS\agent.properties`.
7. If the agent is running on Windows Server 2008 with IIS 7.0, perform the following steps:
  - a) Download the certificate for the KeyPair associated with the Agent HttpsListener
  - b) In Windows Explorer, double-click the certificate to view the certificate information.
  - c) Click **Install Certificate** to start the Certificate Import Wizard, then click **Next**.
  - d) When prompted to select a certificate store, select **Place all certificates in the following store**, then click **Browse**.
  - e) Enable **Show physical stores**, then expand **Trusted Root Certification Authorities** and select **Local Computer**.
  - f) Click **OK**, then click **Next**.
  - g) Click **Finish** to exit the Wizard.
8. Restart Microsoft IIS Server on the system by performing the following steps:
  - a) Launch Internet Information Services (IIS) Manager.
  - b) Navigate to the web server node in the Connections tree.
  - c) In the **Actions** pane, click **Restart**.

**Tip:** Alternatively, the command `iisreset /restart` can be used to restart the IIS service.

### Uninstall

You can remove the PingAccess Agent from an IIS system.

### About this task

**Note:** You can also remove the PingAccess Agent from an IIS system using the Add/Remove Programs option in the Windows control panel.

## Steps

1. Run the `pingaccess-agent-iis.msi` installer.  
The installer displays the available workflows.
2. Select the Remove workflow.

## Configuration

The PingAccess Agent for IIS configuration is managed through the Internet Information Services (IIS) Manager application. During the installation of the agent, a configuration schema extension is added to the `system.webServer` section. This schema extension adds the two configuration options defined in the following table:

Parameter	Definition	Default Value
PaaCertificateDir	String value containing the path to the certificates extracted from the <code>.properties</code> files.	C:\Program Files\Ping Identity\PingAccess Agent for IIS\certs
PaaPropertyFiles	List of <code>.properties</code> files which store configuration data used to connect the agent to the PingAccess engine nodes the agent will communicate with.	C:\Program Files\Ping Identity\PingAccess Agent for IIS\agent.properties

**Note:** It is not necessary to make any changes to these configuration parameters if the steps in the [Installation](#) section were followed.

The configured `agent.properties` files can contain the following parameters:

Parameter	Definition	Default Value
agent.engine.configuration.scheme	The URI scheme used to connect to the engine node. Valid values are <code>http</code> and <code>https</code> .	https
agent.engine.configuration.host	The PingAccess hostname.	The value in the Agent Node's PingAccess Host field.
agent.engine.configuration.port	The port the agent connects to on the PingAccess host. This value is defined in the PingAccess <code>run.properties</code> file.	Defined in the PingAccess Admin UI
agent.engine.configuration.username	The unique agent name that identifies the agent in PingAccess.	Defined in the PingAccess Admin UI
agent.engine.configuration.checkCertificateRevocation	Determines whether the agent performs certificate revocation list checking against the server certificate used by the engine nodes or by a load balancer in front of the engine nodes. A value of 1 enables CRL checking, while a value of 0 disables CRL checking.	Not present by default. Treated as 1 when not specified.
agent.engine.configuration.sharedSecret	The password used to authenticate the agent to the engine.	Defined in the PingAccess Admin UI

Parameter	Definition	Default Value
agent.engine.configuration.bootstrapTruststore	The base64-encoded public certificate used to establish HTTPS trust by the agent to the PingAccess engine.  <b>Note:</b> If you are having difficulty connecting an agent to the PingAccess engine, verify that the Agent Trusted Certificate has been configured correctly in <a href="#">Agent Management</a> .	Generated by PingAccess
agent.engine.configuration.maxConnections	The number of connections a single web server worker process maintains to the PingAccess engine defined in the <code>agent.engine.configuration.host</code> parameter.	10
agent.engine.configuration.timeout	The maximum time (in milliseconds) a request to PingAccess can take from the agent. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.engine.configuration.connectTimeout	The maximum time (in milliseconds) the agent can take to connect to the PingAccess engine. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.cache.missInitialTimeout	The maximum time (in milliseconds) a web server worker process waits for a response to a policy cache request sent to other web server worker processes.	5
agent.cache.broker.publisherPort	The network port web server processes use to publish policy cache requests to other web server worker processes. This port is bound to the localhost network only.	3031
agent.cache.broker.subscriberPort	The network port web server processes use to receive policy cache requests from other web server worker processes. This port is bound to the localhost network only.	3032
agent.cache.maxTokens	The maximum number of tokens stored in the policy cache for a single web server worker process. A value of 0 means there is no maximum.	0

Parameter	Definition	Default Value
agent.cache.disabled	<p>Determines whether caching of policy decisions is enabled or disabled. A value of 1 disables caching, forcing the agent to communicate with the PingAccess host any time a policy decision needs to be made. This option may be desired when using PingAccess 3.1 or earlier with the following rule types:</p> <ul style="list-style-type: none"> <li>• Groovy Script Rule</li> <li>• HTTP Request Rule</li> <li>• Network Range Rule</li> <li>• Time Range Rule</li> </ul> <p><b>Note:</b> PingAccess 3.2 does require the cache be disabled in order to process these rules correctly from an agent.</p> <p>This may also be desirable for custom rules created using the PingAccess SDK that involve data that changes with every request within a resource and session.</p> <p> <b>Warning:</b> Disabling caching has a significant impact on the scalability of the PingAccess Policy servers, as every rule evaluation is processed by the Policy Server. This option should only be used as a last resort because of the performance penalty.</p>	0

Changes to the `agent.properties` file require a restart of the web server.

**Tip:** See the [Performance tuning guide](#) for discussion on improving agent performance.

### Log Configuration

The PingAccess Agent for IIS installer registers the PingAccess-Agent Windows Event Log publisher when the agent is installed. This makes PingAccess Agent log information available in the Windows Event Viewer in the `Applications and Services Logs\PingAccess-Agent` folder.

PingAccess Agent for IIS logs information to one of three potential logs:

Log Description
<p><code>Admin</code> contains general information messages about the module and any error messages that occur during operation. This should be a low-volume log. This log is enabled and visible by default.</p>

Log Description
<p><b>Analytics</b> contains monitoring, performance, and timing information. Entries in this log are useful for diagnosing performance issues. Information about the source of a policy decision for each request. This log is enabled but hidden by default.</p>
<p><b>Debug</b> contains debug-level information about the module's operation. This log should only be enabled at the request of Ping Identity support technicians, as it is a very high volume log and may contain sensitive identity and token information. This log is disabled and hidden by default.</p>

**Note:** To view and enable a log:

1. Click **View > Show Analytic and Debug Logs** in Event Viewer to display all of the logs.
2. Select the log that you want to enable in the console tree.
3. Click **Enable Log** in the Actions pane.

In addition to using the Windows Event Viewer, PingAccess Agent log information is accessible using the PowerShell cmdlet `get-winevent`. For example, in a PowerShell session, the content of these logs can be retrieved using the command:

```
PS> get-winevent -logname PingAccess-Agent/Admin,PingAccess-Agent/
Debug,PingAccess-Agent/Analytic -Oldest
```

## Troubleshooting

The table below lists some potential problems and resolutions you may encounter with the PingAccess Agent for IIS.

Issue	Resolution
The Installer fails to successfully install the agent.	<p>The steps listed in the <a href="#">Manual Installation</a> procedure can be used to validate the installation and allow you to manually complete the installation.</p> <p>You can review the MSI installer log file for the installation to identify errors. The log file is stored in the Temp directory <code>C:\Users\<username>\AppData\Local\Temp</username></code> by default. The filename is not fixed, so you must locate the most recent <code>MSI*.log</code> file. You can direct the installer to log to a specific file by launching the installer using this command:</p> <pre>msiexec /l*v "&lt;location&gt;/paAgentInstaller.log" /i "pingaccess-agent-iis.msi"</pre>
The Uninstall program fails to successfully remove the agent.	Follow the steps in the <a href="#">Manual Removal</a> to remove the configuration for the PingAccess Agent for IIS.
The PingAccess-Agent/Admin log contains the error <code>SSL peer certificate or SSH remote key was not OK(0)</code>	It is likely that the hostname for the PingAccess engine being accessed does not match the hostname in the certificate used by the agent. Verify the certificate configuration, and if necessary, recreate the certificate for the Agent HTTPS Listener and recreate the Agent configuration. See <a href="#">PingAccess User Interface Reference Guide</a> in the PingAccess documentation for more information.

Issue	Resolution
500 series errors accessing protected resources	<p>This can indicate that the PingAccess Agent failed to load, or that the Default Application Pool is stopped. Correct the issue that's causing the module load failure, and then restart the Default Application Pool.</p> <p>One potential cause of this is that the <code>agent.properties</code> file cannot be found or loaded. Ensure that this file is copied over as described in <a href="#">Step 6</a> of the installation procedure.</p>
32-bit application pools crashing	<p>This indicates that IIS attempted to load the PingAccess 64-bit agent module in an application container that is running in 32-bit mode. Modify the <code>applicationHost.config</code> file's <code>PingAccessAgentModule</code> directive in the <code>globalModules</code> section to add the following <code>preCondition</code> directive:</p> <pre data-bbox="574 596 1214 632">preCondition="integratedMode, bitness64"</pre> <p>For example:</p> <pre data-bbox="574 726 1425 890">&lt;globalModules&gt; &lt;add name="PingAccessAgentModule"     image="c:\Program Files\Ping Identity\PingAccess     Agent for IIS\paa-iis-module.dll"     preCondition="integratedMode, bitness64" /&gt; &lt;/globalModules&gt;</pre>
Agent does not start. Application log contains this error: The Module name PingAccessAgentModule path (...) \paa-iis-module.dll returned an error from registration. The data is the error.	<p>This can indicate a corrupted or invalid <code>agent.properties</code> file. Export the <code>agent.properties</code> file from the administrative console and replace the existing file on the IIS system with the new version, as described in <a href="#">Installation</a> on page 314.</p>

Issue	Resolution
<p>Agent receives an unknown protocol error when attempting to contact the administrative node</p>	<p>This can indicate that the operating system is using sha1 for encryption. This protocol is no longer supported by default in PingAccess.</p> <p>We recommend switching to sha256. If you cannot switch to sha256, you can re-enable sha1:</p> <ol style="list-style-type: none"> <li>1. Open the <code>run.properties</code> file.</li> <li>2. Add TLSv1 to the protocol list. For example: <pre data-bbox="602 464 1458 520">tls.default.protocols=<b>TLSv1</b>, TLSv1.1, TLSv1.2</pre> </li> <li>3. Add the SHA entries to the cipher suites list. For example: <pre data-bbox="602 575 1458 1346">tls.default.cipherSuites =   TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256, \   TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256, \   TLS_RSA_WITH_AES_128_GCM_SHA256, \   TLS_RSA_WITH_AES_128_CBC_SHA256, \   TLS_DHE_RSA_WITH_AES_128_GCM_SHA256, \   TLS_EMPTY_RENEGOTIATION_INFO_SCSV, \ <b>TLS_RSA_WITH_AES_128_CBC_SHA, \   TLS_DHE_RSA_WITH_AES_128_CBC_SHA,</b>   \ <b>TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_RSA_WITH_AES_128_CBC_SHA, \   TLS_ECDH_ECDSA_WITH_AES_128_CBC_SHA</b></pre> </li> </ol>

## Validate IIS Configuration

### About this task

For a minimal configuration of the PingAccess Agent for IIS, the following steps outline the changes made during installation that may need to be verified if the installer fails. Use this procedure as a guide for what to check if the installation did not complete successfully.

### Steps

1. Stop Microsoft IIS using the following steps:
  - a) Execute the command `net stop w3svc`.
  - b) Execute the command `net stop was`.

2. Edit `C:\Windows\System32\inetsrv\config\applicationHost.config` and add the following line to the `sectionGroup` container with `name=system.webServer` under `configSections`:

```
<section name="paa" overrideModeDefault="Deny"
  allowDefinition="AppHostOnly" allowLocation="false" />
```

3. Add the following XML block to the `<system.webServer>` element in `C:\Windows\System32\inetsrv\config\applicationHost.config`:

```
<paa>
  <paaCertificateDir value="C:\Program Files\Ping Identity\PingAccess Agent
  for IIS\certs\" />
  <paaPropertyFiles>
    <file path="C:\Program Files\Ping Identity\PingAccess Agent for IIS
  \agent.properties" />
  </paaPropertyFiles>
</paa>
```

4. Open IIS Manager and navigate to **Management > Configuration Editor**. Select the `system.webServer/paa` section and validate that the paths added to `applicationHost.config` are correct.
5. Register the agent module with IIS by performing the following steps:
  - a) Open IIS Manager, then select the web server the agent is being added to.
  - b) Click **Modules**.
  - c) Click **Configure Native Modules**.
  - d) Click **Register** and enter the following information:

Name	PingAccessAgentModule
Path	C:\Program Files\Ping Identity\PingAccess Agent for IIS\paa-iis-module.dll

- e) Click **OK**.
- f) Click **OK**.
- g) Execute the command `iisreset /restart`.

## Manual Installation

### About this task

The following procedure can be used to perform a manual installation or to manually complete a partial installation if the installation failed for some reason.

**Important:** For information about preventing a known issue on systems running application pools in 32-bit compatibility mode, see [Troubleshooting](#).

**Tip:** If you find it necessary to use this procedure due to an installation problem, please open a support ticket so the underlying issue you ran into can be addressed.

### Steps

1. Stop Microsoft IIS using the following steps:
  - a) Execute the command `net stop w3svc`.
  - b) Execute the command `net stop was`.
2. Extract the `pingaccess-agent-iis.msi` installer file from the PA IIS Agent Distribution zip file (`pingaccess-agent-iis-x.x.x.zip`).

3. Extract the MSI installer file's contents using this command:

```
C:\Windows\System32\msiexec /a <full path to pingaccess-agent-iis.msi> /qb
TARGETDIR=<destination path>
```

**Note:** From this step on, this procedure will refer to the target directory as `TARGETDIR`. The files of interest are in `TARGETDIR\PFiles`.

4. Copy `TARGETDIR\PFiles\Ping Identity\` and its contents to `C:\Program Files\`.
5. Download the [Microsoft Visual C++ Redistributable](#) and install it.
6. Add the PingAccess Agent module configuration schema to IIS by executing the following commands:
  - a) `cd C:\TARGETDIR\PFiles\inetsrv\config\schema\`
  - b) `copy paa_schema.xml C:\Windows\System32\inetsrv\config\schema\`
7. Edit `C:\Windows\System32\inetsrv\config\applicationHost.config` and add the following line to the `sectionGroup` container with `name=system.webServer` under `configSections`:

```
<section name="paa" overrideModeDefault="Deny"
allowDefinition="AppHostOnly" allowLocation="false" />
```

8. Add the following XML block to the `<system.webServer>` element in `C:\Windows\System32\inetsrv\config\applicationHost.config`:

```
<paa>
  <paaCertificateDir value="C:\Program Files\Ping Identity\PingAccess Agent
  for IIS\certs\" />
  <paaPropertyFiles>
    <file path="C:\Program Files\Ping Identity\PingAccess Agent for IIS
  \agent.properties" />
  </paaPropertyFiles>
</paa>
```

9. Open IIS Manager and navigate to **Management > Configuration Editor**. Select the `system.webServer/paa` section and validate that the paths added to `applicationHost.config` are correct.

**Note:** If the changes are not present, ensure that you are using a 64-bit text editor. When using a 32-bit text editor, changes to this file will be transparently saved to `%SYSTEMROOT%\SysWOW64\inetsrv\applicationHost.config`.

10. Create a folder named `certs` in `C:\Program Files\Ping Identity\PingAccess Agent for IIS\`
11. Change the permissions of `C:\Program Files\Ping Identity\PingAccess Agent for IIS\certs` to include read and writer permissions for `IIS_IUSRS`. You may need to manually search for this user when modifying the permissions.
12. Register the PingAccess Agent logging publisher by performing the following steps:

- a) Execute the command:

```
C:\Windows\System32\wevtutil im paa-event-logging.xml /rf:"C:\Program
Files\Ping Identity\PingAccess Agent for IIS\paa-iis-module.dll" /
mf:"C:\Program Files\Ping Identity\PingAccess Agent for IIS\paa-iis-
module.dll"
```

- b) Run the following three commands to ensure the logging publisher installed successfully:

```
C:\Windows\System32\wevtutil gl PingAccess-Agent/Admin
C:\Windows\System32\wevtutil gl PingAccess-Agent/Analytic
C:\Windows\System32\wevtutil gl PingAccess-Agent/Debug
```

13. Register the agent module with IIS by performing the following steps:

- a) Open IIS Manager, then select the web server the agent is being added to.
- b) Click **Modules**.
- c) Click **Configure Native Modules**.
- d) Click **Register** and enter the following information:

Name	PingAccessAgentModule
Path	C:\Program Files\Ping Identity\PingAccess Agent for IIS\paa-iis-module.dll

- e) Click **OK**.
- f) Click **OK**.
- g) Execute the command `iisreset /restart`.

14. After IIS has restarted, use IIS Manager to ensure that the Default Application Pool has started.

**Note:** If the Default Application Pool has not started, you will see 500 series server errors when navigating to a Site protected by the agent.

15. Continue the installation from [Step 3](#) of the installation procedure.

## Results

The PingAccess Agent writes log information to the PingAccess-Agent logs in the Event Viewer Application and Services logs. Check these logs for any errors if the agent module does not appear to have loaded.

## Manual Removal

### About this task

In the event that an attempt to remove the agent from a system fails, perform the following procedure:

### Steps

1. Stop Microsoft IIS using the following steps:
  - a) Execute the command `net stop w3svc`.
  - b) Execute the command `net stop was`.
2. Edit `C:\Windows\System32\inetsrv\config\applicationHost.config` and remove the following line from the `sectionGroup` container with `name=system.webServer` under `configSections`:

```
<section name="paa" overrideModeDefault="Deny"
  allowDefinition="AppHostOnly" allowLocation="false" />
```

3. Remove the following XML block from the `<system.webServer>` element in `C:\Windows\System32\inetsrv\config\applicationHost.config`:

```
<paa>
  <paaCertificateDir value="C:\Program Files\Ping Identity\PingAccess Agent
  for IIS\certs\" />
  <paaPropertyFiles>
    <file path="C:\Program Files\Ping Identity\PingAccess Agent for IIS
  \agent.properties" />
  </paaPropertyFiles>
</paa>
```

4. Open IIS Manager and navigate to **Management > Configuration Editor**. Select the `system.webServer/paa` section and validate that the paths were properly removed from `applicationHost.config`.
5. Deregister the agent module with IIS by performing the following steps:

- a) Open IIS Manager, then select the web server the agent is being removed from
- b) Click **Modules**
- c) Click **Configure Native Modules**
- d) Select the `PingAccessAgentModule` registered module, then click **Remove**
- e) Click **OK**
- f) Execute the command `iisreset /restart`

## Release Notes

### Version History

- **Version 1.4** – June 2019
  - Agent SDK for C version 1.2.0
  - Added ability to set policy caching mechanism using a property in the `agent.properties` file
  - Added ability to enable or disable agent processing for a request based on a note field
  - Fixed a potential security issue
- **Version 1.3.2** – November 2018
  - Fixed a potential security issue
- **Version 1.3** – January 2017
  - Added support for IIS 10 on Windows Server 2016.
  - Updated to v1.1.1 of the PingAccess Agent SDK for C.
  - Resolved issue with IIS Preload Enabled setting.
- **Version 1.2.1** – November 2016
  - Added support for the “Preload Enabled” setting in IIS.
  - Security enhancements.
- **Version 1.2** – August 2016
  - Updated to v1.0.1 of the PingAccess Agent SDK for C.
- **Version 1.1.2** – February 2016
  - Addressed issue with custom request headers not being set when URL contains query string parameters.
- **Version 1.1.1** – September 2015
  - Addressed compatibility with the IIS plugin for WebSphere.
- **Version 1.1** – December 2014
  - Added Support for Microsoft Internet Information Services (IIS) 7.0 running on Windows Server 2008.
  - Added Support for Microsoft Internet Information Services (IIS) 7.5 running on Windows Server 2008 R2.
  - Added Support for Microsoft Internet Information Services (IIS) 8.0 running on Windows Server 2012 Datacenter Edition.
  - Corrected a potential security issue related to caching (SECBL007). This security bulletin is available in the Ping Identity Support Portal (<https://ping.force.com/support>).
- **Version 1.0** – July 2014
  - Initial Release.

## PingAccess Agent for NGINX

### Introduction

**Note:** Download the **PingAccess Agent for NGINX** on the [PingAccess Downloads](#) page.

The PingAccess Agent for NGINX is an NGINX module that intercepts requests to the web server's protected resources and evaluates applicable access control policies. These policies are evaluated by either accessing a locally cached policy decision or by querying the PingAccess engine node.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

Within the PingAccess Administration Console, Agent Nodes are configured with information that allows a PingAccess Agent to connect to the engine node to retrieve information about access control policies for resources within that agent's control. An agent configuration has a one-to-many relationship with PingAccess agents, allowing a single agent configuration bootstrap file to be used on multiple web servers within a server farm.

**Tip:** An Agent Node is a shared configuration used by one or more agents, rather than a specific agent instance.

## System Requirements

The PingAccess Agent for NGINX is supported on the following platforms:

- Nginx Plus R15 (1.13.10) running on RedHat Enterprise Linux Server 7 (x86\_64)
- Nginx Plus R16 (1.15.2) running on RedHat Enterprise Linux Server 7 (x86\_64)
- Nginx Plus R17 (1.15.7) running on RedHat Enterprise Linux Server 7 (x86\_64)
- Nginx Plus R18 (1.15.10) running on RedHat Enterprise Linux Server 7 (x86\_64)

## Installation

### Before you begin

This procedure makes the following assumptions:

- The PingAccess NGINX Agent zip content is extracted to the \$PINGACCESS\_AGENT\_NGINX folder.
- The NGINX installation is assumed to live at \$NGINX. In the steps in this procedure, modify the paths specified based on where your NGINX installation and configuration files are located.
- You have downloaded the installation package from the [PingAccess Downloads](#) page.

### About this task

To install the PingAccess Agent for NGINX, perform the following steps:

**Note:** The Agent RPM has required dependencies that may be available via standard repositories. If these dependencies are not available in your Linux version, you can install them using the included

libpam-5\_2-0-5.2.122-32.1.x86\_64.rpm, libsodium18-1.0.11-1.1.x86\_64.rpm and libzmq5-4.3.1-23.6.x86\_64.rpm packages.

## Steps

1. Install the NGINX module:

```
yum install pingaccess-agent-nginx-*.rpm lib*.rpm
```

2. In the PingAccess Console, go to the **Agents** page.
3. Edit a configured agent. If the agent has not yet been created, see the **Agents** section of the [PingAccess User Interface Reference Guide](#).
4. In the shared secret, click the download icon to download the agent properties file.
5. Copy the agent properties file to `$NGINX/paa/agent.properties`.
6. Add the following directive to the NGINX configuration file (`$NGINX/nginx.conf`) to load the PingAccess Agent for NGINX module:

```
load_module modules/nginx_http_paa_module.so;
```

7. Add the following directive to the NGINX configuration file (`$NGINX/nginx.conf`) within the `http {}` block to configure the PingAccess Agent for NGINX module:

```
include $NGINX/paa/http.conf;
```

**Important:** In PingAccess [Manage Agents](#), **PingAccess Host** must match the certificate CN or Subject Alternative Name.

8. Modify the following property in the file `$NGINX/paa/http.conf` in order to enable the PingAccess Agent:

```
paa_enabled on;
```

9. Restart the NGINX server:

- a. `sudo systemctl stop nginx`
- b. `sudo systemctl start nginx`

## Uninstall

You can remove the PingAccess Agent from an NGINX system.

## Steps

Run this command:

```
sudo yum remove pingaccess-agent-nginx.x86_64
```

## Configuration

The PingAccess Agent for NGINX configuration is managed through the `$NGINX/paa/http.conf` configuration file.

This file contains the configuration options defined in the following table:

Parameter	Definition	Default Value
<code>paa_properties_files</code>	Properties file that stores configuration data used to connect the agent to the PingAccess engine nodes.	<code>\$NGINX/paa/agent.properties</code>

Parameter	Definition	Default Value
paa_enabled on off	Value that turns the agent on or off. This property can also be applied to server blocks within the nginx server to control which server block(s) is protected by the agent.	off
paa_upstream	Defines the upstream that will be used by the PingAccess Agent to route policy decision requests to PingAccess policy servers.	pingaccess-policy-server
paa_thread_pool	Defines the thread pool to use for blocking operations performed by the agent. Currently this only includes policy cache lookup operations when using the ZeroMQ multiprocess policy cache.	default

**Note:** It is not necessary to make any changes to `http.conf` if the steps in the [Installation](#) section were followed.

**Note:** Changes to the `paa_upstream` will impact how the agent communicates with PingAccess. Incorrect changes may lead to a non-functional Agent.

**Note:** The 'upstream pingaccess-policy-server' contains the directive 'pingaccess\_servers'. This directive indicates that the servers for the containing upstream are defined by the `agent.properties` file. The agent only allows this directive to be specified for a single upstream.

The configured `agent.properties` files can contain the following parameters:

Parameter	Definition	Default Value
agent.engine.configuration.scheme	The URI scheme used to connect to the engine node. Valid values are <i>http</i> and <i>https</i> .	https
agent.engine.configuration.host	The PingAccess hostname.	The value in the Agent Node's PingAccess Host field.
agent.engine.configuration.port	The port the agent connects to on the PingAccess host. This value is defined in the PingAccess <code>run.properties</code> file.	Defined in the PingAccess Admin UI
agent.engine.configuration.username	The unique agent name that identifies the agent in PingAccess.	Defined in the PingAccess Admin UI
agent.engine.configuration.shared.secret	The password used to authenticate the agent to the engine.	Defined in the PingAccess Admin UI

Parameter	Definition	Default Value
agent.engine.configuration.bootstrapTruststore	The base64-encoded public certificate used to establish HTTPS trust by the agent to the PingAccess engine.  <b>Note:</b> If you are having difficulty connecting an agent to the PingAccess engine, verify that the Agent Trusted Certificate has been configured correctly in <a href="#">Agent Management</a> .	Generated by PingAccess
agent.engine.configuration.maxConnections	The number of connections a single web server worker process maintains to the PingAccess engine defined in the <code>agent.engine.configuration.host</code> parameter.	10
agent.engine.configuration.timeout	The maximum time (in milliseconds) a request to PingAccess can take from the agent. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.engine.configuration.connectTimeout	The maximum time (in milliseconds) the agent can take to connect to the PingAccess engine. If this time is exceeded, the client will receive a generic 500 Server Error response.	30000
agent.cache.missInitialTimeout	The maximum time (in milliseconds) a web server worker process waits for a response to a policy cache request sent to other web server worker processes.	5
agent.cache.broker.publisherPort	The network port web server processes use to publish policy cache requests to other web server worker processes. This port is bound to the localhost network only.	3031
agent.cache.broker.subscriberPort	The network port that web server processes use to receive policy cache requests from other web server worker processes. This port is bound to the localhost network only.	3032
agent.cache.maxTokens	The maximum number of tokens stored in the policy cache for a single web server worker process. A value of 0 means there is no maximum.	0

Parameter	Definition	Default Value
agent.cache.disabled	<p>Determines whether caching of policy decisions is enabled or disabled. A value of 1 disables caching, forcing the agent to communicate with the PingAccess host any time a policy decision needs to be made. This option may be desired when using PingAccess 3.1 or earlier with the following rule types:</p> <ul style="list-style-type: none"> <li>• Groovy Script Rule</li> <li>• HTTP Request Rule</li> <li>• Network Range Rule</li> <li>• Time Range Rule</li> </ul> <p>PingAccess 3.2 and later does not require the cache be disabled in order to process these rules correctly from an agent.</p> <p> <b>Warning:</b> Disabling caching has a significant impact on the scalability of the PingAccess Policy servers, as every rule evaluation is processed by the Policy Server. This option should only be used as a last resort because of the performance penalty.</p>	0
agent.engine.configuration.failover.hostname	<p>The <b>Hostname</b> and <b>Port</b> of the PingAccess server where the agent should send requests in the event of a failover from the PingAccess Host.</p> <p><b>Note:</b> If this parameter is set, the upstream block name in <code>\$NGINX/paa/http.conf</code> needs to be modified to a name that will be found in the certificate associated with the PingAccess Agent HTTPS Listener.</p> <p>For example, if your PingAccess certificate contains name 'pa.nginx', set the upstream name to <code>upstream pa.nginx</code>.</p>	Defined in the PingAccess Admin UI
agent.engine.configuration.failover.retry.timeout	<p>The <b>Retry Timeout</b> for trying a failed PingAccess server.</p>	60

Parameter	Definition	Default Value
agent.engine.configuration.failover.max_retries	The maximum number of retries before considering a PingAccess server unavailable.	2
agent.cache.type	Controls the type of policy cache used by the agent. There are three valid values for this property: <ul style="list-style-type: none"> <li>• <b>AUTO</b> - The AUTO cache type determines the appropriate cache to use based on the number of worker processes. If the number of worker processes is 1, the agent uses the STANDALONE cache. If the number of worker processes is 2 or more, the agent uses the ZMQ cache.</li> <li>• <b>STANDALONE</b> - The STANDALONE cache type does not share policy cache entries across worker processes.</li> <li>• <b>ZMQ</b> - The ZMQ cache type allows the agent to share policy cache entries across all worker processes using ZeroMQ for inter-process communication.</li> </ul>	AUTO

Changes to the `agent.properties` file require a restart of the web server.

**Tip:** See **Agent Tuning** in the PingAccess [Performance tuning reference guide](#) for a discussion on improving agent performance.

## Release Notes

### Version History

- **Version 2.0.1** – June 2019  
Agent SDK for C version 1.2.0
  - Fixed a potential security issue
- **Version 2.0** – February 2019
  - The PingAccess Agent for NGINX now leverages the built-in, event-driven HTTP stack in NGINX to communicate with PingAccess policy servers. Previously, the agent used its own HTTP client (implemented with libcurl) to communicate with PingAccess policy servers. In certain cases, this architecture lead to poor scalability. By using NGINX's built-in, event-driven HTTP stack, the agent is able to achieve superior scalability over previous versions.
  - Fixed a potential security issue
- **Version 1.1.1** – July 2017
  - Support for starting and stopping NGINX via the `systemctl` command
  - Resolved issue with SSL connectivity

- **Version 1.1** – March 2017
  - Updates to meet NGINX certification requirements
- **Version 1.0** – January 2017
  - Initial Release

## PingAccess Agent Protocol

---

### PAAP Overview

The PingAccess Agent Protocol (PAAP) is an HTTP-based protocol for communication and interaction between PingAccess (PA) and PingAccess agents.

An agent typically sits in front of a web application or other protected resource on the web server or load balancer (e.g.: Apache or Microsoft IIS).

PAAP is HTTP-based and utilizes a few custom status codes and headers. One goal of basing the protocol on HTTP is to enable an agent, which runs in an HTTP environment, to utilize concepts and code/libraries already at its disposal to do its job.

The majority of the responsibilities reside within PA. The intent of this protocol is to make the agent a relatively “dumb” agent, largely shielded from the configuration and processing details, and allowing for policies to be maintained centrally in PA. This means that agents do not need to know about the signing and encryption keys used by PA or PingFederate. By following this model, the protocol allows agents and PA to be versioned and upgraded independently of one another.

The protocol described here is supported by PingAccess version 3.0 and higher.

#### Note:

The prefix “vnd-pi-” was chosen for the PAAP protocol headers defined in this document. In this context, “vnd” indicates a vendor extension, and “pi” represents Ping Identity. Custom status codes were selected after consulting the [Hypertext Transfer Protocol \(HTTP\) Status Code Registry](#), with the intention of avoiding any conflicts.

### PingAccess agent protocol flow

The PingAccess agent protocol has a set flow by which requests from clients are evaluated and managed.

The PingAccess agent protocol starts with the client (a web browser, OAuth client, or any type of HTTP client) making a request for an application resource. The agent sits in front of the resource and intercepts the request. To determine what to do with it, the agent forwards a portion of the request to PA. The response from PA instructs the agent whether to allow the original request, as well as any additional actions that should be taken prior to handing it off to the application. It also includes instructions for actions to be performed before sending the corresponding response.

## PingAccess®

The protocol flow goes through these steps:

1. Client request
2. Agent request
3. Agent response
4. Modified client request
5. Client response

### PAAP client request

The PingAccess agent protocol flow begins when the client makes an HTTP 1.1 request to a server where an agent is set up in the filter or interception chain in front of an application or other protected resource.

#### Unauthenticated user request

This request is coming from an unauthenticated user.

```

GET /application/headers HTTP/1.1
Host: http://example.com/

#### OIDC Connect flow request

This request is part of the OpenID Connect flow for authentication. The POST body is not shown for brevity.

```

POST /pa/oidc/cb HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Content-Length: 1557
Cache-Control: max-age=0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q=0.8
Origin: https://rhel-test.englab.corp.pingidentity.com:9031
  
```

```
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_9_4)
AppleWebKit/537.36 (KHTML, like Gecko) Chrome/37.0.2062.120
Safari/537.36
Content-Type: application/x-www-form-urlencoded
Accept-Encoding: gzip,deflate
Accept-Language: en-US,en;q=0.8
Cookie: nonce=b000c6a2-4a03-4bde-be29-956456cd1d2a
```

### Authenticated resource request

This request is an authenticated request for a resource.

```
GET /application/headers HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Cache-Control: max-age=0
Accept: text/html,application/xhtml+xml,application/
xml;q=0.9,image/webp,*/*;q=0.8

```

### PAAP agent request

When the agent intercepts a client request, it makes a correlated request to PA to determine if the request is authorized and what action to take on it.

The agent request is made by the agent after it receives a client request to determine what actions to take. PA returns the agent response to the agent communicating the action. The agent request effectively mirrors the client request, except for the differences described below.

The Request-Line of the agent request is identical to the Request-Line of the client request. Unless otherwise specified below, all headers in the agent request are sent as they appear in the client request.

The message-body of the client request (if any) is omitted from the initial agent request. If PA needs the body, an HTTP 477 response, as defined in the agent response section, is returned. PA will be able to service the vast majority of agent requests without having to see the message body. The body from the initial agent request is omitted because PA will not need it to make a policy decision in most instances, and removing it provides an opportunity for significant performance efficiencies. The HTTP 477 response mechanism provides PA a way to get the body in the less common cases where it is needed.

### HTTP request headers

The following HTTP request headers may require additional agent processing:

#### Content-Length

The Content-Length header in the agent request will have a value matching the message-body of the request being sent. For the initial agent request, which is sent without the message-body, the Content-Length will be zero. A subsequent agent request resulting from a 477 will send a Content-Length that indicates the size of the entity-body of the request, which is the same as in the client request.

#### vnd-pi-expect

This header allows the agent to communicate its needs to PA. “!477” is the only defined value, which tells PA that the agent request contains all the data the agent is capable of sending regarding the client request. PA should never respond with a 477 to an agent request that has “!477” as the value of the `vnd-pi-expect` request header. Note that while [the expect header from RFC 2616](#) with an expectation-extension could convey the same semantics, Ping Identity elected not to use it due to language in the RFC that suggests intermediaries might/should/must reject a request using an expectation-extension they don't understand with a 417.

A simple and effective approach for an agent implementation is to send the initial agent request with no body, a content-length of zero, and omitting the `vnd-pi-expect` header. The header `vnd-pi-expect: !477` is only ever sent when an agent receives a 477 response to its initial request. In other words, the initial agent request never has a `vnd-pi-expect` header, while a second agent request in response to an HTTP 477 response always has `!477` as the value for the `vnd-pi-expect` header.

PA should never respond to a GET request with a 477, but following this standard allows an agent to handle such an occurrence in an appropriate way.

### **vnd-pi-v**

Indicates the version of PAAP the agent is using. The value is “1.0”.

### **vnd-pi-authz**

This header is similar to the [authorization header defined in RFC 2616](#) but is specifically intended to enable an agent to authenticate itself to PA. The syntax for the “credentials” value of the header is the same as the [section 2.1 of The OAuth 2.0 Authorization Framework: Bearer Token Usage](#).

The header looks like this:

```
vnd-pi- authz: Bearer <token>
```

Where `<token>` is a secret shared between PA and the PAA.

In some cases, unrestricted access to the agent protocol at PA might create an information leakage vulnerability. The custom headers returned in the agent response, for example, may reveal internal details of applications or infrastructure that needs to be protected. Potentially worse, the values might reveal content from encrypted WAM tokens or reference access tokens. Authenticating PAAs to PA is one means of mitigating the concern.

Authentication is optional; when it is required is at the discretion of PA. Authentication of the agent to PA is intended to be a static deployment option and, as such, no challenge response constructs are defined. Failed authentication – missing credentials when required or invalid credentials – is indicative of either a configuration problem or unauthorized access attempt. In such circumstances, PA responds with an HTTP 403 and should include the `vnd-pi-authz` header in the response using a quoted string value with human readable information to help troubleshoot and allow for differentiation from an unauthorized end-user. An agent may send the 403 response or a 500 response to the client, depending on which is most appropriate.

### **vnd-pi-resource-cache**

Indicates that for the given host the `vnd-pi-resource-cache` and `vnd-pi-resource-cache-ttl` headers, defined in the caching part of the next section, are to be returned in the agent response. Generally an agent will include this header when it needs to first establish its resource definition cache for a particular host, or when its current cache is stale or invalid. When an agent request includes the `vnd-pi-resource-cache` header, the agent response should include the `vnd-pi-resource-cache` and `vnd-pi-resource-cache-ttl` headers. An agent

must be prepared to handle an agent response that omits those headers. The literal value “requested” can be used by the agent to request the resource cache data. For example:

```
vnd-pi-resource-cache: requested
```

### X-Forwarded-For

The X-Forwarded-For header contains the originating IP address of a client making a request. If no X-Forwarded-For header is present in the client request, it is added to the agent request with a value indicating the IP address of the client making the connection. If an X-Forwarded-For header is present in the client request, the IP address of the client is added to the end of the delimited list of IP addresses this header contains when sent in the agent request.

### Host and X-Forwarded-Host

The agent sets the Host header in the agent request as it appeared in the client request, unless it is unable to easily manipulate the Host header. In the event that it could not modify the Host header, the X-Forwarded-Host header contains the original host requested by the client. If X-Forwarded-Host is already present in the client request, it is sent along unchanged in the agent request.

### X-Forwarded-Proto

If X-Forwarded-Proto is present in the client request, it is sent along unchanged in the agent request. Otherwise, if the scheme used in the client request is different than the agent request (https vs. http), set the X-Forwarded-Proto header in the agent request to the scheme used in the client request. This header can be omitted if the client request and the agent request use the same scheme.

PA determines the requested resource and constructs self-referential URIs using the contents of the request, including the headers listed above. The scheme is determined from the client’s connection and the X-Forwarded-Proto header, with the latter taking precedence when present. The host and port are determined from the Host and X-Forwarded-Host headers, with the latter taking precedence when present.

#### Policy decision request

This request is a policy decision request for an unauthenticated user:

```
GET /application/headers HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q=0.8
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_9_4)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/37.0.2062.120
  Safari/537.36
Accept-Encoding: gzip,deflate,sdch
Accept-Language: en-US,en;q=0.8
Cookie: nonce=6424266c-ca9b-4e1f-9fde-d1860bfa2582
vnd-pi-v: 1.0
X-Forwarded-For: 172.30.3.248
vnd-pi-resource-cache: requested
X-Forwarded-Proto: http
vnd-pi-authz: Bearer Agent:htZ2W39EfAPLQd8w9cRT6y
```

**Agent request without POST body**

This request is an agent request (in this case, the OpenID Connect callback in a web session POST login type) without the POST body included:

```
POST /pa/oidc/cb HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Content-Length: 0
Cache-Control: max-age=0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q=0.8
Origin: https://rhel-test.englab.corp.pingidentity.com:9031
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_9_4)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/37.0.2062.120
  Safari/537.36
Content-Type: application/x-www-form-urlencoded
Accept-Encoding: gzip,deflate
Accept-Language: en-US,en;q=0.8
Cookie: nonce=b000c6a2-4a03-4bde-be29-956456cd1d2a vnd-pi-v: 1.0
X-Forwarded-For: 172.30.3.248
vnd-pi-resource-cache: requested
X-Forwarded-Proto: http
vnd-pi-authz: Bearer Agent:htZ2W39EfAPLQd8w9cRT6y
```

**Agent request with POST body**

This request is a policy decision request with the POST body included. Note the vnd-pi-expect: !477 header that disallows the HTTP 477 agent response to request the body (as it is already included):

```
POST /pa/oidc/cb HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Content-Length: 1557
Cache-Control: max-age=0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,image/webp,*/*;q=0.8
Origin: https://rhel-test.englab.corp.pingidentity.com:9031
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_9_4)
  AppleWebKit/537.36 (KHTML, like Gecko) Chrome/37.0.2062.120
  Safari/537.36
Content-Type: application/x-www-form-urlencoded
Accept-Encoding: gzip,deflate
Accept-Language: en-US,en;q=0.8
Cookie: nonce=b000c6a2-4a03-4bde-be29-956456cd1d2a
vnd-pi-v: 1.0
X-Forwarded-For: 172.30.3.248
vnd-pi-resource-cache: requested
X-Forwarded-Proto: http
vnd-pi-expect: !477
vnd-pi-authz: Bearer Agent:htZ2W39EfAPLQd8w9cRT6y
```

**Authenticated user request**

This request is for a resource by an authenticated user:

```
GET /application/headers HTTP/1.1
Host: http://example.com/
```

response are indicated by one or more of the headers listed in the HTTP 277 headers section.

### **HTTP 277 headers**

These headers can be included in the agent response if the response code HTTP 277 was used.

#### **vnd-pi-set-req-headers**

The value of this header is a comma-delimited list of header names from the agent response to be included as headers for the client request. If any included headers already exist in the client request, the values are overwritten with the values from the corresponding agent response header. If a header is named which is not present in the agent response, it is removed from the client request.

This allows, for example, PA to make user attribute information available to the protected application in the headers, and to guard against header injection by the client. In order to guard against malicious header injection by end users, use this mechanism to expose user data to the application. PA should include all header names used in a given context, even if they have no value, so headers supplied by the client using the same names will be ignored.

#### **vnd-pi-append-req-headers**

The value of this header is a comma-delimited list of header names from the agent response to add to the client request headers. Any existing named headers already present in the client request are not overwritten, but new headers are added with the values from the agent response. If a header is named which is not present in the agent response, no action is taken for that header name in the client request.

#### **vnd-pi-set-req-vars**

The value of this header is a comma-delimited list of header names from the agent response that are to be set in the client request as request scoped variables or attributes in an appropriate manner for the environment in which the agent resides. Examples might include environment variables in Apache or request attributes in a servlet container.

#### **vnd-pi-sub**

This header is used to identify the header that contains the subject or username for the transaction. This typically will be a header also named in vnd-pi-set-req-headers, as those generally expose user information to the backend application via headers in the modified client request. It may name a header not in the vnd-pi-set-req-headers list, if the agent or environment in which it's deployed needs to know the username/subject in a way that differs from header injection to the client request. The vnd-pi-sub header should name a single-valued header, but if it names one with multiple values, the agent should use only one. If vnd-pi-sub names a header which is not present in the agent response, it should be ignored by the agent.

#### **vnd-pi-set-resp-headers**

The value of this header is a comma-delimited list of header names from the agent response which are to be set as headers of the client response. If any of the named headers already exist in the client response, the values are overwritten with the values of those headers from the agent response. If a header is named which is not present in the agent response, it is removed from the client response.

#### **vnd-pi-append-resp-headers**

The value of this header is a comma-delimited list of header names from the agent response which are to be added to the headers of the client response. Any existing named headers already present in the client response are not overwritten, but new headers are

added with the values from the agent response. If a header is named which is not present in the agent response, no action is taken for that header name in the client response.

This allows, for example, PA to set or reset the PA WAM token as a cookie in the user's browser.

In general, for any particular request or response header name, PA should only indicate either a set or an append directive. However, with an agent response, the set directive takes precedence. One way the agent might accomplish that is by applying all append operations first, followed by the set operations.

### Common headers

These headers can be used in an agent response of any status code.

#### vnd-pi-omit-resp-headers

The value of this header is a comma-delimited list of header names from the agent response to omit from the headers in the client response. When present, this list implicitly includes the vnd-pi-omit-resp-headers header.

### Caching

A number of caching directives are aimed at reducing calls from the agent to PA and improving performance.

#### Resource Definition Caching

When the vnd-pi-resource-cache request header is present in the agent request, PA includes the following headers in the agent response. This enables the agent to make initial decisions on handling of client requests without having to consult PA directly.

#### vnd-pi-resource-cache

This is a multi-valued header and, in keeping with [Section 4.2 of RFC 2616](#), the values may be comma-delimited, or multiple message-header fields with the same name may be included. The order of the values is significant and, in servicing future requests based on the cache, an agent should evaluate them in the order they were received.

Each value represents a group of resources and some directives about how the agent should handle requests for URIs within that group of resources. The values are made up of multiple parts delimited by semicolons.

- **path** – The path part defines the path(s) against which requests are matched. The value is one or more space-delimited quoted strings. Each quoted string is a path value, which may contain wildcards using the asterisk (\*) character. So, for example, `path="/app/*"` would match any requested path that starts with `/app/`. While `path="/app1/*" "/app2/*"` would match anything under `/app1/` or `/app2/`. Similarly, `path="*.jpg" *.gif" *.png"` would match anything ending with those common image file extensions. If no wildcard is present, the values must exactly match.
- **cs** – Indicates if the values in the path are case-sensitive. Valid values are Y and N. If this component is omitted, the default value is Y.
- **method** – Indicates the method or methods against which requests are matched. The value is one or more space-delimited method names (i.e. GET, POST, PUT, etc). If this component is omitted, all methods are allowed and should match for the resource.
- **kind** – Indicates the kind of resource and the general level of access control protection which is to be applied to it - i.e. whether access to the resource (and related resources as per the path values) requires an authorization token. Valid values are P, U or C. The value P (meaning 'Protected') says that a token is required for access and the token-type and token-name indicate the token of interest so that the token value can be used

in caching the response and response headers to service future requests. The value U (meaning 'Unprotected') indicates that no token is necessary for access and that any future request (within the cache time-to-live) will be allowed. The value C (meaning 'Consult' with PA) means that the agent must always make an agent request to PA in order to service the client request.

- **token-type** – The token-type part indicates what kind of token was used in making the authorization decision and what token type to use in making future cache queries. Its value is either C or A. A value of C indicates that a cookie was used to make the access control decision, and that future requests with the same cookie value for the cookie named in the token-name part can use the cached content. A value of A indicates that an authorization header was used to make the access control decision, and that future requests with the same credentials for the authorization scheme named by the token-name directive can use the cached content.
- **token-name** – The token-type says what type of token for which to cache specific user details for a particular token. However, there may be more than one token for a particular type in a request. The token-name value disambiguates that situation by specifying which one to use. The token-name value is either the name of a cookie (for WAM) or the name of an authorization scheme (the "Bearer" value for OAuth), when token-type value is C or A, respectively.

**Note:** When this value is a cookie, the cookie name is case-sensitive, as implied by [RFC 6265](#). When this value is the name of an authorization scheme, per [section 1.2 of RFC 2617](#), the value is not case-sensitive. When using the token-name header, ensure that the value follows the appropriate case-sensitivity requirements.

The resource-cache list is valid for and scoped to the host in the client request. When building the resource-cache, PA includes resources associated with the virtual host that matches the host of the request as well as wildcard virtual host resources

### vnd-pi-resource-cache-ttl

The value of the resource cache time-to-live header is an integer indicating the number of seconds from the time the response was sent that the values of the vnd-pi-resource-cache header could be cached and used. For example, the following header instructs the agent to cache the resource definitions for the next ten minutes:

```
vnd-pi-resource-cache-ttl: 600
```

The agent can use the vnd-pi-resource-cache header in an agent request to ask PA for new vnd-pi-resource-cache and vnd-pi-resource-cache-ttl values when the time-to-live on its current resource cache has, or is about to, elapse.

PA provides configurability over the resource cache time-to-live value to balance performance and security goals.

An example vnd-pi-resource-cache response header is shown below. This example tells the client that all requests with a path starting with `/pa/oidc/` are to have the agent make an agent request to PA to determine what to do. Next, it tells PA that requests with a `jpg`, `gif` or `png` suffix are allowed to pass through. Requests for a path that starts with `/canada/` require a PA WAM token which will be a cookie named `PA.cad`. Requests for a path that starts with `/usa/` require a PA WAM token which will be a cookie named `PA.usd`. All other requests, indicated by the slash wildcard path are allowed. Note that the request path is matched against the paths defined in the resource-cache in order from top to bottom. The vnd-pi-resource-cache-ttl tells the agent to use the resource cache for the next hour.

```
vnd-pi-resource-cache: path="/pa/oidc/*"; kind=C
```

```
vnd-pi-resource-cache: path="/*.jpg" "*.gif" "*.png";
  method=GET; kind=U
vnd-pi-resource-cache: path="/canada/*"; cs=N; kind=P; token-
type=C; token-name=PA.cad
vnd-pi-resource-cache: path="/usa/*"; kind=P; token-type=C;
  token-name=PA.usd
vnd-pi-resource-cache: path="/*" ; kind=U
vnd-pi-resource-cache-ttl: 3600
```

Note that the above is semantically equivalent to the following headers where the multiple vnd-pi-resource-cache header fields are combined into one.

```
vnd-pi-resource-cache: path="/pa/oidc/*"; kind=C, path="/*.jpg"
  "*.gif" "*.png"; method=GET; kind=U, path="/canada/*"; cs=N;
  kind=P; token-type=C; token-name=PA.cad, path="/usa/*"; kind=P;
  token-type=C; token-name=PA.usd, path="/*" ; kind=U
vnd-pi-resource-cache-ttl: 3600
```

### Individual token and agent response caching

The resource-cache defined in the previous section gives the agent meta-information about caching data for request handling. This section describes how, in some cases, data from an individual agent response can be cached relative to a particular token and used to service future client requests with the same token so that PA doesn't need to be called on every client request.

The resource-cache defined in the previous section gives the agent directives about how to handle requests based on host, method and path. The agent iterates its resource-cache list in order until it finds a match based on those values. Additional caching can be done for particular kinds of resources as follows.

When the "kind" of the resource-cache is P, a token (as indicated by the token-type and token-name) is required but previous agent responses for a token can be cached for efficiency. If the agent does not have a cached agent response for a particular token value, it must make an agent request to PA in order to determine how to handle the client request. The data from that agent response can then be cached using the value of the indicated token as a key. An empty, null, or missing token should also be considered a valid cache key in order to support the 'anonymous' access use case, where a WAM token is not necessary for access but, if such a token is available, user attributes from it should be exposed to the application. An agent response to a request that does not have the indicated token-type/token-name will likely contain a vnd-pi-set-req-headers directive that names non-existent headers in order to ensure they are stripped from the modified client request. This prevents injection of those header values by the client, even in an 'anonymous' case.

When caching individual agent responses relative to particular tokens, the protocol directives state that the token value is obtained from the client request. However, there is one important special case where, for efficiency, the token value can be obtained from the agent response. That special case is for resources with a "kind" of P and token-type of C that receive a 277 agent response containing a positive vnd-pi-token-cache-ttl header value and avnd-pi-append-req-headers that includes the set-cookie header. Under those conditions, the agent can examine the set-cookie headers for a cookie name matching the token-name of the resource and use the value of that cookie as the token value to cache the agent response. Note that the agent should also exclude that set-cookie header from the cached agent response content. This allows the cache to be established for an individual token in only one agent request to PA when the token in the cookie is updated and set on the client.

Though the token relative caching is primarily intended as an optimization to store and reuse data associated with status code 277 responses, the cache header defined below is valid on any agent response, and agents should be prepared to cache all agent responses, rather than just 277 responses.

In general, individual agent responses for resources of kind of C are not cached. The one exception is the special case of a 477 response code where an agent can cache the 477 (which tells it to send the request

body on the initial agent request along with a !477 value for the vnd-pi-expect header) for a specific request URI, until the vnd-pi-resource-cache-ttl passes.

A kind value of U indicates that no agent request or response is necessary for the client request, so no additional caching is necessary.

### **vnd-pi-token-cache-ttl**

Indicates the number of seconds from the time the agent response is issued that it can be cached relative to a specific token value. The agent must make a new agent request if the TTL on the cache entry of an individual token has expired, or if no cache entry exists.

The TTL should correlate to the life of the token itself - i.e. the time-to-live must be shorter than the expiration, and it needs to also allow for updates to the inactivity timeout within a reasonable threshold.

There are many tradeoffs involved, thus PA enables tuning and configuration options for the TTL directive.

In the event that the token is empty, null, or missing (i.e., the “anonymous” use case), the value of vnd-pi-token-cache-ttl can be the same as the value of the vnd-pi-resource-cache-ttl.

### **Early Cache Invalidation**

PA may include the following header in an agent response to instruct the agent to invalidate its cache. The agent may need to do this, for example, as a result of configuration changes.

### **vnd-pi-cache-invalidated**

The value of this header is a numeric value representing the number of seconds from 1970-01-01T0:0:0Z UTC (the epoch) until the UTC date/time of the cache invalidation event. The value is an indicator of the most recent event that would trigger an invalidation of the cache associated with the host (or X-Forwarded-Host) of the agent request correlated to the agent response in which this header appears. An agent may ignore an invalidation directive for a timestamp that it has already processed.

It is difficult for PA to know the cache state of any particular agent or group of agents. So it is not reasonable to expect PA to identify the exact responses that should include the cache invalidation directive. Use of the timestamp as the header value allows PA to send the vnd-pi-cache-invalidated more indiscriminately while allowing the agent to relatively easily determine if it needs to, or already has, taken action with respect to a specific invalidation event.

### **Change Propagation and Caching**

An agent populates and expunges its cache over time. As a result, configuration changes in PA may take some time to propagate, and may yield a mixed set of old and new behavior.

The invalidation directive set via the vnd-pi-cache-invalidated header on the agent response is intended to provide some help seeing changes take effect inside the TTL window. Though caching does reduce the number of calls made from an agent to PA, there are still many requests that will necessitate the call and allow the vnd-pi-cache-invalidated header to be sent to an agent.

#### **OpenID Connect authentication**

This response is passed through to the client to begin the OpenID Connect authentication process. The status and headers are passed directly through to the client.

### Request for POST body

This response requests the POST body that was omitted from the initial agent request:

```

HTTP/1.1 477 Request Body Required
Date: Wed, 17 Sep 2014 23:10:35 GMT
Content-Length: 0
vnd-pi-resource-cache: path="/pa/*";kind=C,path="/
application/*" "/application";cs=Y;kind=P;token-
type=C;token-name=PA.post,path="/protected/*" "/

httpbin/headers*";cs=Y;kind=P;token-type=C;token-
name=PA.post,path="/httpbin/*" "/httpbin";cs=Y;kind=P;token-
type=C;token-name=PA.post
vnd-pi-resource-cache-ttl: 900

```

### Redirect

This response issues a redirect. The status code and headers are passed directly through to the client.

```

HTTP/1.1 302 Found
Date: Wed, 17 Sep 2014 23:10:36 GMT
Content-Length: 0
Location: http://example.com/application/headers
Set-Cookie:

type=C;token-name=PA.post
vnd-pi-resource-cache-ttl: 900

```

**Grant access**

This response grants access and allows the client request through to the application with the appropriate application headers set and with the caching directives.

```
HTTP/1.1 277 Allowed
Date: Wed, 17 Sep 2014 23:10:36 GMT
Content-Length: 0
vnd-pi-resource-cache: path="/pa/*";kind=C,path="/
application/*" "/application";cs=Y;kind=P;token-
type=C;token-name=PA.post,path="/protected/*" "/
protected";cs=Y;kind=P;token-type=C;token-name=PA.post,path="/
httpbin/headers*" ;cs=Y;kind=P;token-type=C;token-
name=PA.post,path="/httpbin/*" "/httpbin";cs=Y;kind=P;token-
type=C;token-name=PA.post
vnd-pi-resource-cache-ttl: 900
vnd-pi-token-cache-ttl: 300
USER: joe
vnd-pi-sub: USER
vnd-pi-set-req-headers: USER
```

**PAAP modified client request**

If the agent response status is 277, the client request is modified according to the directives in the agent response and the request is passed along to the application or allowed to continue processing in the HTTP processing pipeline of the environment in which the agent is deployed.

**Additional HTTP headers**

This example shows the additional HTTP headers added as specified by PA.

```
GET /application/headers HTTP/1.1
Host: http://example.com/
Connection: keep-alive
Cache-Control: max-age=0
Accept: text/html,application/xhtml+xml,application/
xml;q=0.9,image/webp,*/*;q=0.8
User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10_9_4)
AppleWebKit/537.36 (KHTML, like Gecko) Chrome/37.0.2062.120
Safari/537.36
Accept-Encoding: gzip,deflate,sdch
Accept-Language: en-US,en;q=0.8
Cookie:
PA.post=eyJraWQwQ0I0iJhcCI0ImFsZyI6IkVMTjU2In0.eyJ6b25laW5mbyI6IkFtZXJpY2F0L05ld19ZL
j0BddLoGeVdqWD35n9ZxPhphEHFe7tfQ6onKAjRdXLR5rtwPBkJHkLaTLd8Yqcsf0izVw
USER: joe
```

**PAAP client response**

The client response is the HTTP response corresponding to the client request.

If the agent response status code is anything other than 277, its content is sent back to the client as the content of the client response, minus any headers identified for exclusion. If the agent response status code is 277, the client request is passed to the protected application, and the client response is the response from the application with any header modifications indicated by the agent response.

**Pass-through from agent response**

This client response shows the direct pass-through of the status code and headers from the agent response.

See the agent response OpenID Connect authentication example for a related example.

```

## PingAccess Agent SDK for C

---

### Preface

This documentation provides technical guidance for using the PingAccess Agent SDK for C. Developers can use this guide along with the API documentation for the SDK and sample source code to implement custom agents that use the PingAccess Agent Protocol to integrate with a PingAccess policy server.

### Intended Audience

This guide is intended for application developers and system administrators responsible for implementing a C-based PingAccess agent. The reader should be familiar with C software development principles and practices. It describes the use of the SDK within a sample Agent for Apache.

### Additional documentation

The SDK documentation provides detailed reference information for developers. After unzipping the `pingaccess-agent-c-sdk-version.zip` package, the API documentation can be accessed with a web browser by viewing the file `AGENT_SDK_C_HOME/apidocs/index.html`. The current version of the API documentation may also be found online at <https://www.pingidentity.com/content/dam/developer/documentation/pingaccess/agent-c-sdk/1-1-4/apidocs/index.html>

## Introduction

The PingAccess Agent SDK for C provides an API and sample code to enable developers to build agents for C or C++-based application and web servers.

### Supported platforms

- RedHat Enterprise Linux Server 6 (32 bit)
- RedHat Enterprise Linux Server 6 (64 bit)
- RedHat Enterprise Linux Server 7 (32 bit)
- RedHat Enterprise Linux Server 7 (64 bit)
- SUSE Linux Enterprise Server 11 SP4 (64 bit)
- SUSE Linux Enterprise Server 12 SP2 (64 bit)

The PingAccess Agent SDK for C provides an API and sample code to enable developers to build agents for C-based application and web servers. Agents provide access management features to their containing server by relying on central PingAccess servers over the PingAccess Agent Protocol. The [PingAccess Agent Protocol Specification](#) is available from the Ping Identity support portal.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

The PingAccess Agent SDK for C consists of the following components:

#### SDK (C Agent)

The SDK is a set of C header files that represent the interface to the library that implements the PingAccess Agent Protocol.

#### C Agent libraries

The C libraries implement the PingAccess Agent Protocol. There are binaries for Red Hat Enterprise Linux 6/7 as well as for Windows.

#### PingAccess Agent SDK for C API documentation

Each of the interfaces defined in the header files is fully documented.

#### Apache Agent Sample

`<AGENT_SDK_FOR_C_HOME>/sample`: The Apache Agent Sample demonstrates how the SDK integrates into Apache as an Apache module that is integrated with the Apache request processing workflow. The provided source code and module configuration provide a functional example for how to integrate the SDK into an existing web application. The sample can be modified in-place and recompiled using `make` to test customizations to the Sample code for your environment.

**Note:** This sample code demonstrates how to implement the PingAccess Agent as an Apache module and has been qualified in the following environments:

- Red Hat Enterprise Linux 6 (RHEL6), 64-bit
- Red Hat Enterprise Linux 7 (RHEL7), 64-bit

The Apache Agent itself is production-quality and can be used either as-is or as a starting point for further development. While Ping Identity provides this as a sample, the only versions that are fully supported in production are the precompiled versions available from the Ping Identity download site.

The sample includes instructions for how to configure the sample as a PingAccess Agent to protect websites within its scope. Note that further hardening of the Apache server configuration or of the sample configuration file may be required.

If you need assistance using the PingAccess Agent SDK for C, visit the Ping Identity [Support Center](#) ([ping.force.com/Support](http://ping.force.com/Support)) to see how we can help you with your application. You may also engage the Ping Identity Professional Services team for assistance with developing customizations.

## Getting Started with the PingAccess Agent SDK for C

### Agent SDK for C directory structure

The PingAccess Agent SDK for C directory contains the following subdirectories:

<code>/</code>	This directory contains the Agent SDK for C <code>README.md</code> , which contains information developers will need in order to develop agents using the SDK. It also contains <code>ReadMeFirst.pdf</code> and <code>Legal.pdf</code> , which contain general information about the kit and third-party licenses used by components of the SDK.
<code>/apidocs</code>	API documentation for the SDK. Open <code>index.html</code> to access the API documentation content.
<code>/include</code>	Agent SDK header files.
<code>/lib</code>	32-bit and 64-bit libraries for Red Hat Enterprise Linux 6/7 and Windows, including third-party dependencies required by the SDK.
<code>/sample</code>	Sample source code for an agent for Apache. This sample agent uses the SDK, and includes a sample configuration file for Apache to use the sample agent to enforce authentication and access control policies.

### Agent SDK for C sample code

The Agent SDK for C sample code is available both in the SDK distribution and on github at <https://github.com/pingidentity/pa-agent-c-sdk-sample-apache>.

Before building the sample code, ensure you have the PingAccess Agent SDK for C archive, the GNU `make` utility and associated compiler utilities installed with your compiler, and Apache and its development libraries.

The sample uses Apache and assumes that the PingAccess Agent SDK for C can be referenced as a dependency. For more details about specific dependencies and requirements, as well as instructions on how to build the sample code, see `AGENT_SDK_C_HOME/sample/readme.md`.

## Release notes

- **Version 1.2 - June 2019**
  - Fixed a potential security issue.
- **Version 1.1.5 - February 2019**
  - Added support for FreeBSD 8
- **Version 1.1.4 - October 2018**
  - Fixed potential security issues.
- **Version 1.1.3 - August 2018**
  - Updated version of libcurl to fix an issue where libcurl was only checking the first SAN in the server certificate.
  - Fixed a potential security issue.
- **Version 1.1.2 - March 2017**
  - Added support for:
    - SUSE Linux Enterprise Server 11 SP4 (x86\_64)
    - SUSE Linux Enterprise Server 12 SP2 (x86\_64)
- **Version 1.1.1 - January 2017**
  - Established a workaround for a [known issue](#) in the Network Security Services library that results in a memory leak when the agent closes a HTTPS connection to a PingAccess policy server. For more information, see [this KB article](#).
  - Fixed an issue where duplicate headers were being included in the backend request to the PingAccess Engine causing the request for content to be blocked by the agent.
- **Version 1.1 - November 2016**
  - Added policy server failover support. Policy server failover support is only provided by the SDK when using the libcurl HTTP client.
- **Version 1.0.2 - September 2016**
  - Fixed an issue where agents could not communicate with PingAccess servers using a certificate that is signed by a certificate authority because the CRL Distribution Point extension is missing. This issue is limited to agents on Windows deployments.
  - Addressed a potential security vulnerability. This issue is limited to Windows deployments.
- **Version 1.0.1 - May 2016**
  - Fixed an issue with ZeroMQ policy cache where a terminated process could cause a condition that resulted in unexpected CPU utilization.
- **Version 1.0 - April 2016**
  - Initial Release.

## PingAccess Agent SDK for Java

---

### Preface

This document provides technical guidance for using the PingAccess Agent SDK for Java. Developers can use this guide along with the Javadocs for the Java Agent API and sample source code to implement the PingAccess Agent Protocol in custom agents.

## Intended audience

This guide is intended for application developers and system administrators responsible for implementing a Java PingAccess Agent. The reader should be familiar with Java software-development principles and practices. It describes the use of the SDK within a sample Java Servlet Filter.

## Additional documentation

The Java Agent API Javadocs provide detailed reference information for developers. After unzipping the `pingaccess-agent-java-sdk-1.1.3.zip` package, the Javadocs can be accessed with a web browser by viewing the file `<AGENT_SDK_JAVA_HOME>/apidocs/index.html`.

## Introduction

The PingAccess Agent SDK for Java provides an API and sample code to enable developers to build agents for Java-based application and web servers. Agents provide access management features to their containing server by relying on central PingAccess servers over the PingAccess Agent Protocol. The [PingAccess Agent Protocol Specification](#) is available from the Ping Identity support portal.

The process used when a PingAccess Agent is added to the policy decision process is as follows:

1. The client accesses a resource. If the user is already authenticated, this process continues with step 5.
2. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then redirects the client to PingFederate to establish a session.
3. The user logs in, and PingFederate creates the session.
4. The client is then redirected back to the resource.
5. The agent asks PingAccess for instructions. PingAccess checks the URL policy and determines that it is a protected resource. PingAccess then checks the session token and determines that it is valid.
6. If session revocation is enabled, PingAccess checks and updates the central session revocation list. If the session is valid, the agent is instructed to set identity HTTP headers.

The PingAccess Agent SDK for Java consists of the following components:

### Java Agent API (Java Agent)

`pingaccess-agent-java-api-1.1.3.0.jar`:  
The Java Agent API is a set of classes that implement the PingAccess Agent Protocol.

### PingAccess Agent SDK for Java

`pingaccess-agent-java-sdk-1.1.3.zip`:  
The PingAccess Agent SDK for Java package.

### Servlet Filter Sample

`<AGENT_SDK_FOR_JAVA_HOME>/sample`: The Servlet Filter Sample demonstrates how the Java Agent API integrates into a Java Servlet container. The provided source code, logging configuration and deployment descriptor provide a functional example for how to integrate the Java Agent API into an existing web application. The sample can be modified in place and recompiled using Maven to test customizations to the Servlet Filter Sample code for your environment.

**Note:** This sample code demonstrates how to implement a servlet filter and has been qualified on Apache Tomcat 7. The filter itself is production quality and can be used either as-is or as a starting point for further development. Application configuration within the sample demonstrates how to associate the filter with a servlet (namely, in

web.xml). Further hardening of this file or the application server configuration may be required.

If you need assistance using the PingAccess Agent SDK for Java, visit the Ping Identity [Support Center](https://pingidentity.com/support) (ping.force.com/Support) to see how we can help you with your application. You may also engage the Ping Identity Global Client Services team for assistance with developing customizations.

## Agent SDK directory structure

The PingAccess Agent SDK for Java directory (pingaccess-agent-java-sdk-1.1.3) contains the following:

<code>/apidocs</code>	The Javadocs for the Java Agent API. Open <code>index.html</code> in this directory to access the Javadocs content.
<code>/dist</code>	The directory containing <code>pingaccess-agent-java-api-1.1.3.0.jar</code>
<code>/sample</code>	A directory containing <code>src</code> and <code>target</code> directories for building a Java Servlet Filter. This filter uses the Java Agent API, an <code>agent.properties</code> configuration exported from PingAccess, and the <code>init-params</code> from the web application <code>web.xml</code> file to enforce resource policy decisions configured in PingAccess.

## Agent SDK prerequisites

Before you start, ensure you have the Java SDK, [Apache Maven](https://maven.apache.org) (maven.apache.org) and an application server (e.g. Apache Tomcat) installed. The sample uses Apache Maven and assumes that the Java Agent API can be referenced as a dependency. It references Ping Identity's public Maven repository, located at:

```
http://maven.pingidentity.com/release
```

If Internet access is unavailable, there are two other ways to reference the Java Agent API. First, once Apache Maven is installed, install the Java Agent API into your local dependency repository by executing the following command:

```
mvn install:install-file -Dfile=<AGENT_SDK_JAVA_HOME>/dist/pingaccess-agent-java-api-1.1.3.0.jar -DgroupId=com.pingidentity -DartifactId=pingaccess-agent-java-api -Dversion=1.1.3.0 -Dpackaging=jar
```

Alternatively, update the dependency in your `pom.xml` to point to the local installation:

```
<dependency>
  <groupId>com.pingidentity</groupId>
  <artifactId>pingaccess-agent-java-api</artifactId>
  <version>1.1.3.0</version>
  <scope>system</scope>
  <systemPath><AGENT_SDK_JAVA_HOME>/dist/pingaccess-agent-java-api-1.1.3.0.jar</systemPath>
</dependency>
```

With either of these options, replace `<AGENT_SDK_JAVA_HOME>` with the absolute path to the unzipped `pingaccess-agent-java-sdk-1.1.3.0` directory.

## How to install the servlet filter sample

### Before you begin

Ensure you have the PingAccess Agent SDK for Java, Apache Maven, and Apache Tomcat. These instructions assume that you are using Apache Tomcat.

### About this task

- The servlet filter sample is installed under `<AGENT_SDK_JAVA_HOME>/sample`.
- A deployed version of the servlet filter is under `<AGENT_SDK_JAVA_HOME>/sample/target/agent-sample`.

For the initial setup of the web application, we assume you already have Tomcat or another application server set up on the same machine hosting PingAccess. Out of the box, PingAccess generates self-signed server certificates for listeners servicing runtime ports with the hostname `localhost`. By default, the servlet filter sample configures the Java Agent (Java Agent API) to use "strict" certificate checking for communications with PingAccess. The Java Agent will not be able to communicate with PingAccess over HTTPS if it is not also on `localhost` because of strict hostname checking. If PingAccess already has a server certificate configured with a valid hostname other than `localhost`, then you can deploy the Java Agent into a container on another system.

If you cannot setup the application server on the same system as an existing PingAccess service, and that PingAccess deployment still uses the default `localhost` server certificate for the Agent port, there is another option. You can change the default `strict` certificate checking in `agent-sample/WEB-INF/web.xml` to `test`. Please see the comments in `agent-sample/WEB-INF/web.xml` for more detail.

The `agent-sample` (servlet filter sample) web application is meant to demonstrate the features of the Java Agent within the context of a functional, standalone sample application. The servlet filter sample uses the Java Agent to intercept requests bound for sample servlet and will accept or reject them based on the configured PingAccess policy. The sample servlet only prints out headers, cookies, and other parameters it receives in the request.

### Steps

1. In the Tomcat `webapps` directory, create a directory called `ROOT`.
2. Copy the `WEB-INF`, `META-INF`, and `assets` contents from `/sample/target/agent-sample/` into `webapps/ROOT`.

This sample servlet filter must run as `/` to properly carry out the OpenID Connect workflow.

3. In the Tomcat `bin` directory, create a script called `setenv.sh` (Linux) or `setenv.bat` (Windows) with the following contents:

- For Linux:

```
export CATALINA_OPTS="-Dlog4j.configurationFile=<PATH_TO_TOMCAT_ROOT>/webapps/ROOT/WEB-INF/logs/log4j2.xml -Dserver.log.file=<PATH_TO_TOMCAT_ROOT>/webapps/ROOT/WEB-INF/logs/server.log"
```

- For Windows:

```
set CATALINA_OPTS=="-Dlog4j.configurationFile=<PATH_TO_TOMCAT_ROOT>/webapps/ROOT/WEB-INF/logs/log4j2.xml -Dserver.log.file=<PATH_TO_TOMCAT_ROOT>/webapps/ROOT/WEB-INF/logs/server.log"
```

The Agent servlet filter logging is configured in `webapps/ROOT/WEB-INF/logs/log4j2.xml`, and outputs to `webapps/ROOT/WEB-INF/logs/server.log`

4. If running Tomcat on Linux, execute the command `chmod a+x setenv.sh` to make this script executable.
5. Configure a PingAccess Agent.
6. Configure an Application and associate the new Agent with it.
7. When configuring an Agent through the PingAccess administration console, it automatically exports the agent properties file. Copy the downloaded properties file to `webapps/ROOT/WEB-INF/agent-config/agent.properties`.

**Important:** If Tomcat is running on Java version 7, some version 8 cipher suites are unavailable. This may lead to errors.

To work around this issue, edit `agent.properties` to remove the following cipher suites from `agent.ssl.ciphers`:

- `TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256`
- `TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256`
- `TLS_RSA_WITH_AES_128_GCM_SHA256`
- `TLS_DHE_RSA_WITH_AES_128_GCM_SHA256`

8. Start Tomcat
9. Start a browser and navigate to `http://<HOST>:<PORT>/sample`

The values for `<HOST>` and `<PORT>` here need to match the Tomcat configuration in use.

**Note:** If your Tomcat server is not set up to use HTTPS, ensure that any related Web Sessions do not have the **Secure** option enabled.

## PingAccess Agent SDK for Java Release History

### Version 1.1.3 - July 2018

#### Resolved issues

- Fixed an issue where site cookies were not being set properly for HTTP redirects in the servlet container environment (e.g., Tomcat).
- Fixed an issue where an error was being generated by the SDK sample implementation of `ClientHttpServletRequest.getHeaders` when calling a header that does not exist.

### Version 1.1.2 - June 2017

#### Resolved issues

- Fixed an issue where the Java agent was handling the PingAccess `set-cookie` header incorrectly.
- Fixed an issue where the Java agent wasn't correctly processing multiple `set-cookie` headers sent by PingAccess.
- Fixed an issue where the SDK sample implementation was not correctly enforcing the PingAccess Agent Protocol directives when the `ClientHttpServletRequest.getCookies` method was called. This resulted in a discrepancy between the cookie request headers returned from the `getHeader*` methods and the `getCookies` method.

### Version 1.1.1 - April 2017

#### Resolved issues

- Fixed an issue where unknown attributes should be ignored

- Fixed an issue where percent-encoded sequences in resource paths were being handled incorrectly
- Fixed an issue where an "Index out of bounds" exception occurs if a cookie value is "".

### Version 1.1 - August 2015

#### Resolved issues

- Fixed an issue where OAuth API response headers were getting trimmed
- Fixed an issue where the Java Agent enforced the requirement of a username and shared secret
- Fixed an issue where the Agent was not handling a 477 response correctly
- Initial Release

### Version 1.0 - June 2015

## PingAccess Addon SDK for Java

---

### Preface

This document provides technical guidance for using the PingAccess Add-on SDK. Developers can use this guide, in conjunction with the installed Javadocs, to extend the functionality of the PingAccess server.

**Important:** A restart of PingAccess is required after the deployment of any custom plugins written in Java.

#### Intended audience

This guide is intended for application developers and system administrators responsible for extending PingAccess. The reader should be familiar with Java software-development principles and practices. It describes the development of:

- SiteAuthenticators
- Rules
- Identity mappings
- Load balancing strategies
- Locale override service

#### Additional documentation

- The PingAccess Javadocs provide detailed reference information for developers. The Javadocs can be accessed with a web browser by viewing the file `PA_HOME/sdk/apidocs/index.html`.

### Introduction

The PingAccess Add-on SDK provides extension points that let users customize certain behaviors of PingAccess to suit their needs. This SDK provides the means to develop, compile, and deploy custom extensions to PingAccess.

The PingAccess Add-on SDK provides the following extension points:

#### RuleInterceptor

An interface for developing custom Rule implementations to control authorization logic in policies.

#### SiteAuthenticatorInterceptor

An interface for developing custom Site Authenticators to control how PingAccess

	(operating as a proxy) is able to integrate with web servers or services it is protecting.
<b>IdentityMappingPlugin</b>	An interface for developing custom Identity Mappings to provide user identity information to an Application within PingAccess.
<b>LoadBalancingPlugin</b>	An interface for developing custom Load Balancing strategies that provide the logic for load balancing requests to Target Hosts configured for a Site.
<b>LocaleOverrideService</b>	An interface for developing custom logic for resolving the locale of a request used for localization.

If you need assistance using the SDK, visit the Ping Identity [Support Center](https://ping.force.com/Support) (ping.force.com/Support) to see how we can help you with your application. You may also engage the Ping Identity Global Client Services team for assistance with developing customizations.

## Get started with the SDK

This section describes the directories and build components that comprise the SDK and provides instructions for setting up a development environment.

### SDK directory structure

The PingAccess SDK directory (*PA\_HOME/sdk*) contains these files and directories.

- *README.md* – Contains an overview of the SDK contents.
- */samples/README.md* – Contains an overview of the steps necessary to build and use the samples.
- */samples/Rules* – Contains a maven project with example plug-in implementations for Rules showing a wide range of functionality. You may use these examples for developing your own implementations.
- */samples/Rules/README.md* – Contains the details of the Rules samples.
- */samples/SiteAuthenticator* – Contains a maven project with example plug-in implementations for Site Authenticators. You may use these examples for developing your own implementations.
- */samples/SiteAuthenticator/README.md* – Contains the details of the Site Authenticator samples.
- */samples/IdentityMappings* – Contains a maven project with example plug-in implementations for Identity Mappings. You may use these examples for developing your own implementations.
- */samples/IdentityMappings/README.md* – Contains the details of the IdentityMappings samples.
- */samples/LoadBalancingStrategies* – Contains a maven project with example plug-in implementations for Load Balancing Strategies. You may use these examples for developing your own implementations.
- */samples/LoadBalancingStrategies/README.md* – Contains the details of the LoadBalancingStrategies samples.
- */samples/LocaleOverrideService* – Contains a maven project with example plug-in implementations for the Locale Override Service. You may use these examples for developing your own implementations.
- */samples/LocaleOverrideService/README.md* – Contains the details of the LocaleOverrideService samples.

### SDK prerequisites

These prerequisites must be met before you use the Addon SDK for Java.

Before you start, ensure you have the Java SDK and [Apache Maven](#) installed. The samples use Apache Maven and assume that the PingAccess SDK can be referenced as a dependency. They reference Ping Identity's public maven repository, located at:

```
http://maven.pingidentity.com/release
```

If Internet access is unavailable, update the `pingaccess-sdk` dependency in your `pom.xml` to point to the local installation.

```
<dependency>
  <groupId>com.pingidentity.pingaccess</groupId>
  <artifactId>pingaccess-sdk</artifactId>
  <version>4.0.1.3</version>
  <scope>system</scope>
  <systemPath><PA_HOME>/lib/pingaccess-sdk-4.2.0.0.jar</systemPath>
</dependency>
<dependency>
  <groupId>javax.validation</groupId>
  <artifactId>validation-api</artifactId>
  <version>1.0.0.GA</version>
  <scope>system</scope>
  <systemPath>PA_HOME/lib/validation-api-1.0.0.GA.jar</systemPath>
</dependency>
<dependency>
  <groupId>org.slf4j</groupId>
  <artifactId>slf4j-api</artifactId>
  <version>1.7.4</version>
  <scope>system</scope>
  <systemPath>PA_HOME/lib/slf4j-api-1.7.4.jar</systemPath>
</dependency>
<dependency>
  <groupId>org.slf4j</groupId>
  <artifactId>slf4j-log4j12</artifactId>
  <version>1.7.4</version>
  <scope>system</scope>
  <systemPath>PA_HOME/lib/slf4j-log4j12-1.7.4.jar</systemPath>
</dependency>
```

Replace `PA_HOME` with the path to the PingAccess installation.

### How to install the SDK samples

You can install rule and site authenticator SDK samples.

- Before you begin, ensure you have the Java SDK and Apache Maven installed.
- Each sample type is installed separately:
  - For the Rules samples, navigate to `PA_HOME/sdk/samples/Rules`
  - For the Site Authenticators samples, navigate to `PA_HOME/sdk/samples/SiteAuthenticator`
- From the sample's directory, run the command: `$ mvn install`
  - This builds the samples, runs their tests, and copies the resulting jar file from the target directory to the `PA_HOME/lib` directory.

```
jsmith-MBP-2:Rules jsmith$ mvn install

## Create your own plugins

You can create your own plugins from scratch using the Addon SDK.

Generally, the following steps are taken to implement a plugin:

1. Create a new, empty Maven project. The root directory of the Maven project is referred to as `<PLUGIN_HOME>`.
2. Copy the `pom.xml` from the appropriate sample provided in `<PA_HOME>/sdk/samples`.

**Note:** For example, if you were creating a Rule, you would copy the `pom.xml` from `<PA_HOME>/sdk/samples/Rules/` to `<PLUGIN_HOME>/`.

3. Modify the `groupId`, `artifactId`, `name`, and `version` in the copied `pom.xml` file as appropriate.
4. Create a Java class that implements the plugin interface from the SDK in the `<PLUGIN_HOME>/src/main/java/com/yourpackagename` directory. This interface is referred to as a Service Provider Interface (SPI).

**Note:** For example, if you are implementing a custom Rule, the class should implement the `RuleInterceptor` SPI.

For each SPI, base classes are provided that simplify the implementation of the SPI.

5. Create a provider-configuration file for the plugin SPI containing the fully-qualified class name for the class created in the previous step.

**Note:** For example, if you are implementing a custom Rule, you'll create a file called `<PLUGIN_HOME>/META-INF/services/com.pingidentity.pa.sdk.policy.RuleInterceptor` and its contents will be the FQCN of the class.

6. Build the Maven project to obtain a jar containing the plugin implementation.
7. Copy the jar to `<PA_HOME>/lib`.

**Important:** After copying a custom plugin jar to the PingAccess lib, a restart of PingAccess is required to complete the deployment of the custom plugin.

The following sections provide the details required to complete these steps for each type of plugin:

- [Rule details](#)
- [Site authenticator details](#)
- [Identity mapping details](#)
- [Load balancing strategy details](#)
- [Locale override service details](#)

### Rule details

If you do not need to integrate with a Third-Party Service, use the following SPIs and base classes:

#### SPI

```
com.pingidentity.pa.sdk.policy.RuleInterceptor
```

#### Provider-configuration file

```
<PLUGIN_HOME>/META-INF/services/
com.pingidentity.pa.sdk.policy.RuleInterceptor
```

**Base Classes**

```
com.pingidentity.pa.sdk.policy.RuleInterceptorBase
```

If you need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.policy.AsyncRuleInterceptor
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/  
com.pingidentity.pa.sdk.policy.AsyncRuleInterceptor
```

**Base Classes**

```
com.pingidentity.pa.sdk.policy.AsyncRuleInterceptorBase
```

**Site authenticator details**

If you do not need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.siteauthenticator.SiteAuthenticatorInterceptor
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/  
com.pingidentity.pa.sdk.siteauthenticator.SiteAuthenticatorInterceptor
```

**Base Classes**

```
com.pingidentity.pa.sdk.siteauthenticator.SiteAuthenticatorInterceptorBase
```

If you need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.siteauthenticator.AsyncSiteAuthenticatorInterceptor
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/  
com.pingidentity.pa.sdk.siteauthenticator.AsyncSiteAuthenticatorInterceptor
```

**Base Classes**

```
com.pingidentity.pa.sdk.siteauthenticator.AsyncSiteAuthenticatorInterceptorBase
```

**Identity mapping details**

If you do not need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.identitymapping.IdentityMappingPlugin
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/  
com.pingidentity.pa.sdk.identitymapping.IdentityMappingPlugin
```

**Base Classes**

```
com.pingidentity.pa.sdk.identitymapping.IdentityMappingPluginBase  
com.pingidentity.pa.sdk.identitymapping.header.HeaderIdentityMappingPlugin
```

If you need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.identitymapping.AsyncIdentityMappingPlugin
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/
com.pingidentity.pa.sdk.identitymapping.AsyncIdentityMappingPlugin
```

**Base Classes**

```
com.pingidentity.pa.sdk.identitymapping.AsyncIdentityMappingPluginBase
```

**Load balancing strategy details**

If you do not need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.ha.lb.LoadBalancingPlugin
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/
com.pingidentity.pa.sdk.ha.lb.LoadBalancingPlugin
```

**Base Classes**

```
com.pingidentity.pa.sdk.ha.lb.LoadBalancingPluginBase
```

If you need to integrate with a Third-Party Service, use the following SPIs and base classes:

**SPI**

```
com.pingidentity.pa.sdk.ha.lb.AsyncLoadBalancingPlugin
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/
com.pingidentity.pa.sdk.ha.lb.AsyncLoadBalancingPlugin
```

**Base Classes**

```
com.pingidentity.pa.sdk.ha.lb.AsyncLoadBalancingPluginBase
```

**Locale override service details**

A Locale Override Service cannot integrate with a Third-Party Service so the following SPIs and base classes are used for all implementations:

**SPI**

```
com.pingidentity.pa.sdk.localization.LocaleOverrideService
```

**Provider-configuration file**

```
<PLUGIN_HOME>/META-INF/services/
com.pingidentity.pa.sdk.localization.LocaleOverrideService
```

**Base Classes**

No base classes are provided

**Integrating with third-party services**

The Addon SDK includes the ability for a custom plugin to integrate with external, third-party services via HTTP.

This section provides a high-level overview of utilizing this functionality from a custom plugin.

- [Obtaining the HTTP client instance](#) on page 361
- [Obtaining a handle to a third-party service](#) on page 361
- [Making a HTTP call to a third-party service](#) on page 362
- [Base classes](#) on page 363
- [Sample plugins](#) on page 363

## Obtaining the HTTP client instance

PingAccess provides access to a HTTP client utility interface, `HttpClient`, via dependency injection. Plugins are expected to obtain an instance of this interface using an approach like the following:

```
public class DocumentationPlugin // interfaces and base classes omitted for
    brevity
{
    private HttpClient httpClient;

    // ... other code omitted ...

    @Inject
    public void setHttpClient(HttpClient httpClient)
    {
        this.httpClient = httpClient;
    }

    // ... other code omitted ...
}
```

## Obtaining a handle to a third-party service

Given a `HttpClient` instance, a plugin will also need a handle to a Third-Party Service to make an outbound HTTP call to the service represented by the Third-Party Service administrative configuration object. This handle is an instance of the `ThirdPartyServiceModel` class and is specified to the `HttpClient` in its `send` method.

There are two different ways to obtain a `ThirdPartyServiceModel` instance:

- [Administrator-configured third-party services](#)
- [Third-party services for the OAuth authorization server and OIDC provider](#)

### Administrator-configured third-party services

The PingAccess Administrative UI and API allow administrators to define the communication configuration for an external service by defining a Third-Party Service. These configuration objects can then be associated with custom plugins via their configuration.

To enable a plugin's configuration to reference a Third-Party Service, it should define a field in the configuration with the type of `ThirdPartyServiceModel`. Here is an example:

```
private static class Configuration extends SimplePluginConfiguration
{
    // ... other code omitted ...

    @UIElement(order = 30,
        type = ConfigurationType.SELECT,
        label = "Risk Authorization Service",
        modelAccessor = ThirdPartyServiceModelAccessor.class,
        required = true)
    @NotNull
    private ThirdPartyServiceModel riskAuthzService;

    // ... other code omitted ...

    public ThirdPartyServiceModel getRiskAuthzService()
    {
        return riskAuthzService;
    }

    public void setRiskAuthzService(ThirdPartyServiceModel
        riskAuthzService)
```

```

    {
        this.riskAuthzService = riskAuthzService;
    }
}

```

The important items in this example:

- The `modelAccessor` attribute of the `UIElement` must be set to `ThirdPartyServiceModelAccessor`
- The field in the plugin configuration class must be of type `ThirdPartyServiceModel`

### Third-party services for the OAuth authorization server and OIDC provider

In addition to providing a way for an administrator to configure a plugin to use an arbitrary Third-Party Service, PingAccess allows a plugin to use a third-party service that represents the OAuth Authorization Server or OIDC Provider. The benefit of leveraging this functionality is that a plugin can require access to either of these services without requiring the administrator to configure the plugin to use those services.

Similar to the previous section, the plugin obtains a `ThirdPartyServiceModel` instance that is a handle to the OAuth Authorization Server or OIDC Provider by indicating this requirement in its plugin configuration class. However, the mechanism is a bit different, as shown in the following example:

```

private static class Configuration extends SimplePluginConfiguration
{
    // ... other code omitted ...

    private ThirdPartyServiceModel oidcProvider;

    // ... other code omitted ...

    public ThirdPartyServiceModel getOidcProvider()
    {
        return oidcProvider;
    }

    @Inject
    @OidcProvider
    public void setOidcProvider(ThirdPartyServiceModel oidcProvider)
    {
        this.oidcProvider = oidcProvider;
    }
}

```

The setter for the `oidcProvider` field is annotated with the `@OidcProvider` annotation.

If the `@OidcProvider` annotation includes a parameter, that parameter specifies a required endpoint defined by the OIDC Provider metadata of the current Token Provider. When the plugin is instantiated, the validation for the `@OidcProvider` parameter will pass only if the specified endpoint is a valid HTTP URI in the OIDC Provider Metadata. For example, this annotation will require the `backchannel_authentication` URI:

```
@OidcProvider("backchannel_authentication")
```

### Making a HTTP call to a third-party service

With an instance of `HttpClient` and an instance of `ThirdPartyServiceModel` in hand, a plugin can make a HTTP call to the external service represented by the `ThirdPartyServiceModel`. Here is an example method

that makes a GET request to a resource on the external service with a path of `/data` and a query string of `page=1`:

```
private static CompletionStage<ClientResponse> sendRequest(HttpClient
    httpClient,

    ThirdPartyServiceModel model)
{
    Headers headers = ClientRequest.createHeaders();
    headers.setAccept(Collections.singletonList("application/json"));

    ClientRequest request = new ClientRequest(Method.GET,
                                              "/data?page=1",
                                              headers);

    return httpClient.send(request, model);
}
```

The result of the `HttpClient send` method is a `CompletionStage`. A `CompletionStage` is returned because `PingAccess` is performing the HTTP call asynchronously and as a result, handling of the result of the call needs to be performed by callbacks registered with the `CompletionStage`.

You can use the `getRequestUri()` method to stand in for the endpoint. This can be useful if the endpoint is not known during development. For example:

```
ClientRequest request = new ClientRequest(Method.GET,
                                          model.getRequestUri().get(),
                                          headers);
```

The `RequestUri` is set by the `@OidcProvider("RequestUri")` annotation, and is unset if the `@OidcProvider("RequestUri")` annotation is not present.

For a more complete example of using the `HttpClient` to make an external HTTP call, refer to the sample SDK plugins packaged with the `PingAccess` distribution.

### Base classes

The SDK provides the following base classes to make it easier to implement a plugin that leverages the `HttpClient` interface. They all provide access to a `HttpClient` instance via a `getHttpClient` method.

- `AsyncRuleInterceptorBase`
- `AsyncSiteAuthenticatorInterceptorBase`
- `AsyncIdentityMappingPluginBase`
- `AsyncLoadBalancingPluginBase`

### Sample plugins

The use of the `HttpClient` and `ThirdPartyServiceModel` classes are demonstrated in the following samples provided in the `PingAccess` distribution:

- `RiskAuthorizationRule`, a `Rule` that obtains a risk score from an external, risk service as well as leveraging the OAuth Authorization Server to obtain an OAuth access token used to access the risk service.
- `MetricBasedPlugin`, a `Load Balancing Strategy` that obtains host capacity metadata from an external service.

## Implementation guidelines

These sections provide specific programming guidance for developing custom interfaces.

Note that the information is not exhaustive – consult the Javadocs to find more details about interfaces discussed here as well as additional functionality.

**Important:** A restart of PingAccess is required after the deployment of any custom plugins written in Java.

## Logging

Use the SLF4j API for logging activities in your module. Documentation on using SLF4j is available on the [SLF4j website](#).

## Lifecycle

The plugins and the implementation of a PluginConfiguration can be instantiated for a number of reasons and at many times. For example, with a RuleInterceptor here is what happens before the RuleInterceptor is available to process user requests:

- The Rule annotation on the implementation class of the RuleInterceptor is interrogated to determine which PluginConfiguration instance will be instantiated.
- The following is performed on RuleInterceptor and PluginConfiguration. Which of these is handled first is not defined.
  - The bean will be provided to Spring for Autowiring.
  - The bean will be provided to Spring for post construction initialization. (See PostConstruct)
- PluginConfiguration.setName(String) is called.
- PA attempts to map the incoming JSON configuration to the PluginConfiguration instance.
- ConfigurablePlugin.configure(PluginConfiguration) is called.
- Validator.validate(Object, Class[]) method is invoked and provided to the RuleInterceptor.
- The instance is then made available to service end user requests, such as RequestInterceptor.handleRequest(com.pingidentity.pa.sdk.http.Exchange) and ResponseInterceptor.handleResponse(com.pingidentity.pa.sdk.http.Exchange)

## Injection

Before they are put into use, Rules, SiteAuthenticators, and their defined PluginConfigurations are passed through Spring's Autowiring and initialization. To future-proof any code against changes in PingAccess, we recommend that Spring not be used as a dependency. Use the annotation javax.inject.Inject for any injection.

### Classes available for injection

Currently, injection is available for the following classes:

- com.pingidentity.pa.sdk.util.TemplateRenderer

### Differences between Rules for Agents and Sites

Rules may be applied to applications associated with Agents or Sites. Some features of the SDK are not available to rules that are applied to agents. Rules that use features only available to sites should be marked as only applying to sites. This is done by setting the destination element of the rule annotation to the value {RuleInterceptorSupportedDestination.Site}

Rules that apply only to agents are limited in the following ways:

- The handleResponse method is not called.
- The request body is not present.
- The Exchange.getDestinations list is empty and modifying the destination list has no effect.

As with rules that use features only available to sites, rules that only apply to agents should be marked as only applying to agents. To do this, set the destination element of the rule annotation to the value {RuleInterceptorSupportedDestination.Agent}.

## PingAccess Addon SDK for Java Migration Guide

Plugins built against the Java Addon SDK for PingAccess 5.0 are now required to be built with JDK 8, as the SDK for PingAccess 5.0 uses Java 8 features. Previously, plugins could be built with either JDK 7 or JDK 8.

The following sections provide a detailed description of the changes, organized by package. Where relevant, code examples show how to port existing code to account for the changes in the SDK APIs.

- [General changes](#) on page 365
- [com.pingidentity.pa.sdk.http](#) on page 368
- [com.pingidentity.pa.sdk.identity](#) on page 386
- [com.pingidentity.pa.sdk.identitymapping.header](#) on page 386
- [com.pingidentity.pa.sdk.policy](#) on page 386
- [com.pingidentity.pa.sdk.services](#) on page 393
- [com.pingidentity.pa.sdk.siteauthenticator](#) on page 393
- [com.pingidentity.pa.sdk.ui](#) on page 394
- [com.pingidentity.pa.sdk.user](#) on page 394
- [com.pingidentity.pa.sdk.util](#) on page 394

### General changes

#### Prevent modification to Request in Response chain

Starting in PingAccess 5.0, any modifications made to a Request or its header fields during response processing will now result in a warning log message and the modification operation being ignored. Previously, PingAccess would log a warning message about the modification but still allow the modification operation to complete.

#### Retrieving Key Pair and Trusted Certificate Group configuration data

In the previous version of the SDK, a SDK plugin accessed the configuration data of a Key Pair or Trusted Certificate Group configured via the Administrative API by annotating a field in the plugin's PluginConfiguration class with a JsonDeserialize annotation, specifying the appropriate custom deserializer from the SDK. For example:

```
public class Configuration extends SimplePluginConfiguration
{
    @JsonDeserialize(using = PrivateKeyDeserializer.class)
    KeyStore.PrivateKeyEntry keyPair;

    @JsonDeserialize(using = TrustedCertificateGroupDeserializer.class)
    Collection<X509Certificate> certificateGroup;
}
```

In the current version of the SDK, this mechanism has changed to be less error-prone as well as to provide access to more properties of the Key Pairs and Trusted Certificate Groups. The previous Configuration class should be ported to the following:

```
public class Configuration extends SimplePluginConfiguration
{
    KeyPairModel keyPair;

    TrustedCertificateGroupModel certificateGroup;
}
```

The KeyPairModel#getPrivateKeyEntry method provides access to the KeyStore.PrivateKeyEntry object for the corresponding Key Pair in the administrative configuration. The TrustedCertificateGroupModel#getCertificates method provides access to the Collection of X509Certificate

objects in the corresponding Trusted Certificate Group in the administrative configuration. Refer to the JavaDoc for each of these classes for more information.

Related to this change, the provided implementations of ConfigurationModelAccessor, PrivateKeyAccessor and TrustedCertificateGroupAccessor, have been updated to use these new classes. Both classes have also been moved to new packages. PrivateKeyAccessor has also been renamed to KeyPairAccessor.

#### BEFORE:

```
import com.pingidentity.pa.sdk.accessor.PrivateKeyAccessor;
import com.pingidentity.pa.sdk.accessor.TrustedCertificateGroupAccessor;

// ... class definition omitted ...

private void invokePrivateKeyAccessorGet(
    PrivateKeyAccessor accessor,
    String id)
{
    KeyStore.PrivateKeyEntry keyPair = accessor.get(id);
}
private void invokeTrustedCertificateGroupAccessorGet(
    TrustedCertificateGroupAccessor accessor,
    String id)
{
    Collection<X509Certificate> certificates = accessor.get(id);
}
```

#### AFTER:

```
import
    com.pingidentity.pa.sdk.accessor.certgroup.TrustedCertificateGroupModel;
import com.pingidentity.pa.sdk.accessor.keypair.KeyPairAccessor;

// ... class definition omitted ...

private void invokePrivateKeyAccessorGet(
    KeyPairAccessor accessor,
    String id)
{
    KeyStore.PrivateKeyEntry keyPair = accessor.get(id)

    .map(KeyPairModel::getPrivateKeyEntry)
                                .orElse(null);
}

private void invokeTrustedCertificateGroupAccessorGet(
    TrustedCertificateGroupAccessor accessor,
    String id)
{
    Collection<X509Certificate> certificates = accessor.get(id)
        .map(TrustedCertificateGroupModel::getCertificates)
        .orElse(null);
}
```

#### Changes to validation of PluginConfiguration instances

In the previous version of the SDK, the ConfigurablePlugin#configure method was invoked and passed a PluginConfiguration instance. The ConfigurablePlugin was expected to assign the specified PluginConfiguration instance to a field annotated with the javax.validation.Valid annotation. After the configure method returned, PingAccess passed the ConfigurablePlugin instance to a javax.validation.Validator for further validation.

If setup correctly, this logic allows `javax.validation.Constraint` annotations to be used to declare the validation to be applied to fields in a `PluginConfiguration` implementation, ensuring the configuration was valid as well as providing validation error message to `PingAccess` to provide to administrators using the Administrative API or UI.

However, if the `ConfigurablePlugin#configure` method needed to post-process the specified `PluginConfiguration` instance, the method needed to duplicate all the validation declared on the fields of the `PluginConfiguration`.

To remove the need for this duplication of validation logic, `PingAccess` will now validate the `PluginConfiguration` instance with a `javax.validation.Validator` prior to passing the instance to the `ConfigurablePlugin#configure` method.

Further, the `ConfigurablePlugin` no longer needs to annotate the field used to hold the `PluginConfiguration` instance. The field is still necessary to implement the `ConfigurablePlugin#getConfiguration` method.

The following example `ConfigurablePlugin` implementation demonstrates this change:

```
public class ValidationExample
    implements ConfigurablePlugin<ValidationExample.Configuration>
{
    // @Valid annotation no longer required
    private Configuration configuration;

    @Override
    public void configure(Configuration configuration) throws
    ValidationException
    {
        this.configuration = configuration;

        // With the previous version of the SDK, these assertions were not
        // guaranteed to be true, despite the javax.validation.Constraint
        // annotations enforcing these conditions.
        //
        // In the current version of the SDK, these assertions are guaranteed
        // to be true because they are enforced by the
    javax.validation.Constraint
    the
        // PluginConfiguration validation is performed before invoking the
        // configure method.
        //
        // The end result is that plugins can remove duplicated validation
        // logic from the configure method if further post-processing of the
        // configuration needs to be performed.
        assert(configuration.getAttributeName() != null);
        assert(configuration.getAttributeName().length() > 0);
        assert(configuration.getAttributeName().length() <= 16);
        assert(configuration.getAttributeValue() != null);
    }

    @Override
    public Configuration getConfiguration()
    {
        return configuration;
    }

    static class Configuration extends SimplePluginConfiguration
    {
        @NotNull
        @Size(min = 1,
            max = 16,
```

```

        message = "Attribute name length must be between 1 and 16
characters")
    private String attributeName;

    @NotNull
    private String attributeValue;

    public String getAttributeName()
    {
        return attributeName;
    }

    public void setAttributeName(String attributeName)
    {
        this.attributeName = attributeName;
    }

    public String getAttributeValue()
    {
        return attributeValue;
    }

    public void setAttributeValue(String attributeValue)
    {
        this.attributeValue = attributeValue;
    }
}
}
}

```

### com.pingidentity.pa.sdk.http

#### com.pingidentity.pa.sdk.http.Body

The Body interface has changed to require an explicit read of data before invoking methods to obtain that data. Previously, methods to obtain the data would result in an implicit read of the data. The following code examples illustrate this change in semantics.

As the updated JavaDoc for the Body interface indicates, plugins should avoid interrogating a Body object unless absolutely necessary because reading a Body object's data into memory can impact the scalability of PingAccess. As plugin code is updated, evaluate whether the Body object needs to be used by the plugin.

#### Using the `Body#read` method

##### **BEFORE:**

```

private void invokeRead(Body body) throws IOException
{
    body.read();
}

```

##### **AFTER:**

```

private void invokeRead(Body body) throws AccessException
{
    try
    {
        body.read();
    }
    catch (IOException e)
    {
        throw new AccessException("Failed to read body content",
            HttpStatus.BAD_GATEWAY,

```

```

        e);
    }
}

```

Using the `Body#getContent` method:

**BEFORE:**

```

private void invokeGetContent(Body body) throws IOException
{
    byte[] content = body.getContent();
}

```

**AFTER:**

```

private void invokeGetContent(Body body) throws AccessException
{
    invokeRead(body); // see the Body#read code example for this
    method
    byte[] content = body.getContent();
}

```

Using the `Body#getBodyAsStream` method:

**BEFORE:**

```

private void invokeGetBodyAsStream(Body body) throws IOException
{
    InputStream stream = body.getBodyAsStream();
}

```

**AFTER:**

```

private void invokeGetBodyAsStream(Body body) throws
    AccessException
{
    invokeRead(body); // see the Body#read code example for this
    method
    InputStream stream = body.newInputStream();
}

```

**Note** the rename of the method from `getBodyAsStream` to `newInputStream`.

Using the `Body#write` method:

**BEFORE:**

```

private void invokeWrite(Body body, BodyTransferrer
    bodyTransferrer) throws IOException
{
    body.write(bodyTransferrer);
}

```

**AFTER:**

This functionality is no longer supported. To obtain the content of the `Body`, read the content into memory using the `Body#read` method and then invoke `Body#getContent` or `Body#newInputStream`.

Using the `Body#getLength` method

**BEFORE:**

```
private void invokeGetLength(Body body) throws IOException
{
    int length = body.getLength();
}
```

**AFTER:**

```
private void invokeGetLength(Body body) throws AccessException
{
    invokeRead(body); // see the Body#read code example for this
    method
    int length = body.getLength();
}
```

Using the Body#getRaw method:**BEFORE:**

```
private void invokeGetRaw(Body body) throws IOException
{
    byte[] rawBody = body.getRaw();
}
```

**AFTER:**

This functionality is no longer supported. This method used to provide access to the content as it appeared on the wire, which required complicated handling if the body content used a chunked Transfer-Encoding. Use Body#getContent instead.

**com.pingidentity.pa.sdk.http.BodyFactory**Using the BodyFactory#continuousBody method**BEFORE:**

```
private void invokeContinuousBody(BodyFactory bodyFactory, byte[]
content)
{
    Body body = bodyFactory.continuousBody(content);
}
```

**AFTER:**

```
private void invokeContinuousBody(BodyFactory bodyFactory, byte[]
content)
{
    Body body = bodyFactory.createInMemoryBody(content);
}
```

**BEFORE:**

```
private void invokeContinuousBody(BodyFactory bodyFactory,
InputStream in)
{
    Body body = bodyFactory.continuousBody(in);
}
```

**AFTER:**

A Body instance can no longer be created from an InputStream using the BodyFactory class. Instead, a plugin should read the contents of the InputStream into a byte array and provide the byte array to BodyFactory#createInMemoryBody.

**com.pingidentity.pa.sdk.http.Constants**

The constants available from this class have been removed from the SDK. Plugins using these constants should maintain their own constants with the needed values.

**com.pingidentity.pa.sdk.http.Exchange**

A handful of methods have been removed from the Exchange.

Further, the mechanism for storing data on the Exchange via properties has been enhanced to make it easier to write type-safe code when working with Exchange properties.

*Using the Exchange#getCreationTime method*

**BEFORE:**

```
Calendar creationTime = exchange.getCreationTime();
```

**AFTER:**

```
Calendar creationTime = Calendar.getInstance();
creationTime.setTime(Date.from(exchange.getCreationTime()));
```

**NOTE:** If a Calendar object is not required, consider using the Instant object returned from the getCreationTime method directly instead of converting it into a Calendar object.

*Using the Exchange#getDestinations method*

**BEFORE:**

```
List<String> destinations = exchange.getDestinations();
```

**AFTER:**

This functionality is no longer supported. Consider using the Exchange#getTargetHosts method to obtain similar information from the Exchange.

*Using the Exchange#getOriginalHostHeader method*

**BEFORE:**

```
String originalHostHeader = exchange.getOriginalHostHeader();
```

**AFTER:**

This functionality is no longer supported. Consider using the Exchange#getUserAgentHost method to obtain similar information from the Exchange. The getUserAgentHost method leverages the PingAccess HTTP requests configuration to determine the Host header value sent by the user agent.

*Using the Exchange#getOriginalHostHeaderHost method*

**BEFORE:**

```
String host = exchange.getOriginalHostHeaderHost();
```

**AFTER:**

This functionality is no longer supported. Consider using the `Exchange#getUserAgentHost` method to obtain similar information from the Exchange. The `getUserAgentHost` method leverages the PingAccess HTTP requests configuration to determine the Host header value sent by the user agent.

*Using the `Exchange#getOriginalHostHeaderPort` method*

**BEFORE:**

```
String port = exchange.getOriginalHostHeaderPort();
```

**AFTER:**

This functionality is no longer supported. Consider using the `Exchange#getUserAgentHost` method to obtain similar information from the Exchange. The `getUserAgentHost` method leverages the PingAccess HTTP requests configuration to determine the Host header value sent by the user agent.

*Using the `Exchange#getOriginalRequestBaseUri` method*

**BEFORE:**

```
String originalRequestBaseUri =
    exchange.getOriginalRequestBaseUri();
```

**AFTER:**

This functionality is no longer supported. A possible replacement is as follows:

```
String originalRequestBaseUri = exchange.getUserAgentProtocol() +
                                "://" +
                                exchange.getUserAgentHost();
```

*Using the `Exchange#getProperties` method*

**BEFORE:**

```
Map<String, String> properties = exchange.getProperties();
```

**AFTER:**

This functionality is no longer supported. Properties should be obtained individually from the Exchange.

*Using the `Exchange#getRequestBaseUri` method*

**BEFORE:**

```
String requestBaseUri = exchange.getRequestBaseUri();
```

**AFTER:**

This functionality is no longer supported. A possible replacement is as follows:

```
String requestBaseUri = exchange.getUserAgentProtocol() +
                                "://" +
                                exchange.getUserAgentHost();
```

*Using the `Exchange#getRequestScheme` method*

**BEFORE:**

```
String requestScheme = exchange.getRequestScheme();
```

**AFTER:**

This functionality is no longer supported. A possible replacement is as follows:

```
String requestScheme = exchange.getUserAgentProtocol() + "://";
```

*Using the Exchange#getUser method*

**BEFORE:**

```
User user = exchange.getUser();
```

**AFTER:**

The User interface is no longer supported. Use the Identity interface instead. It can be retrieved via the Exchange#getIdentity method.

*Using the Exchange#setUser method*

**BEFORE:**

```
private void invokeSetUser(Exchange exchange, User user)
{
    exchange.setUser(user);
}
```

**AFTER:**

This functionality is no longer supported. The identity associated with an Exchange cannot be replaced.

*Using the Exchange#setSourceIp method*

**BEFORE:**

```
private void invokeSetSourceIp(Exchange exchange, String
    sourceIp)
{
    exchange.setSourceIp(sourceIp);
}
```

**AFTER:**

This functionality is no longer supported. This value cannot be changed.

*Using the Exchange#setProperty method*

**BEFORE:**

```
private void invokeSetProperty(Exchange exchange, String
    propertyKey, String value)
{
    exchange.setProperty(propertyKey, value);
}
```

**AFTER:**

```
private void invokeSetProperty(Exchange exchange,
    ExchangeProperty<String>
    propertyKey,
    String value)
{
    exchange.setProperty(propertyKey, value);
}
```

See the JavaDoc for ExchangeProperty for instructions on creating an ExchangeProperty object.

Using the Exchange#getProperty method

**BEFORE:**

```
private void invokeGetProperty(Exchange exchange, String
    propertyKey)
{
    Object propertyValueObj = exchange.getProperty(propertyKey);
    if (propertyValueObj instanceof String)
    {
        String propertyValue = (String) propertyValueObj;
    }
}
```

**AFTER:**

```
private void invokeGetProperty(Exchange exchange,
    ExchangeProperty<String> propertyKey)
{
    String propertyValue =
        exchange.getProperty(propertyKey).orElse(null);
}
```

**NOTE:** Exchange#getProperty now returns an Optional object instead of the Object directly.

**com.pingidentity.pa.sdk.http.Header**

This deprecated class has been replaced by the Headers interface. A Headers object can be created via a HeadersFactory obtained from the ServiceFactory#headersFactory method. The majority of methods on Header have counterparts on the Headers interface. See the JavaDoc for the Headers interface for more information.

**com.pingidentity.pa.sdk.http.HeaderField**

This class is now final and cannot be extended.

Constructing a HeaderField

**BEFORE:**

```
private HeaderField createHeaderField(String line)
{
    return new HeaderField(line);
}
```

**AFTER:**

```
private HeaderField createHeaderField(String line)
{
    String name = line.substring(0, line.indexOf(':'));
    String value = (line.substring(line.indexOf(":") +
    1)).trim();

    return new HeaderField(name, value);
}
```

**NOTE:** Parsing an HTTP header field line can be error prone, consider if the plugin can be avoid having to parse an HTTP header field line.

Using the HeaderField#setHeaderName method:

**BEFORE:**

```
private void invokeSetHeaderName(HeaderField field)
{
    field.setHeaderName(new HeaderName("X-Custom"));
}
```

**AFTER:**

This functionality is no longer supported. A HeaderField's name is set upon construction and cannot be changed.

*Using the HeaderField#getApproximateSize method:*

**BEFORE:**

```
int approximateSize = field.getApproximateSize();
```

**AFTER:**

This method has been removed. The value returned by the method can still be computed:

```
int approximateSize = 2 * (4 +
    field.getHeaderName().toString().length() +
    field.getValue().length());
```

**com.pingidentity.pa.sdk.http.Headers**

A few methods on the Headers interface have been updated to use the Instant class, instead of Date.

*Using the Headers#getDate method*

**BEFORE:**

```
Date date = headers.getDate();
```

**AFTER:**

```
Date date = Date.from(headers.getDate());
```

*Using the Headers#setDate method*

**BEFORE:**

```
private void invokeSetDate(Headers headers, Date date)
{
    headers.setDate(date);
}
```

**AFTER:**

```
private void invokeSetDate(Headers headers, Date date)
{
    headers.setDate(date.toInstant());
}
```

*Using the Headers#getLastModified method*

**BEFORE:**

```
SimpleDateFormat format = new SimpleDateFormat("E, dd MMM yyyy
HH:mm:ss z",
                                             Locale.ENGLISH);

String lastModified = headers.getLastModified();
if (lastModified != null)
{
    Date lastModifiedDate = format.parse(lastModified);
}
```

**AFTER:**

```
Date lastModifiedDate = Date.from(headers.getLastModified());
```

Using the Headers#setLastModified method**BEFORE:**

```
private void invokeSetLastModified(Headers headers, Date date)
{
    SimpleDateFormat format = new SimpleDateFormat("E, dd MMM
yyyy HH:mm:ss z",
                                             Locale.ENGLISH);

    headers.setLastModified(format.format(date));
}
```

**AFTER:**

```
private void invokeSetLastModified(Headers headers, Date date)
{
    headers.setLastModified(date.toInstant());
}
```

**com.pingidentity.pa.sdk.http.HeadersFactory**Using the HeadersFactory#createFromRawHeaderFields method**BEFORE:**

```
private void invokeCreateFromRawHeaderFields(HeadersFactory
factory,
                                             List<String> fields)
throws ParseException
{
    Headers headers = factory.createFromRawHeaderFields(fields);
}
```

**AFTER:**

This functionality is no longer supported. Consider if the plugin can create HeaderFields directly and utilize the HeadersFactory#create method.

**com.pingidentity.pa.sdk.http.HttpStatus**

The HttpStatus enum was converted to a final class. Common HttpStatus instances are defined as constants on HttpStatus.

Using the HttpStatus#getLocalizationKey method

**BEFORE:**

```
String localizationKey = status.getLocalizationKey();
```

**AFTER:**

This functionality is no longer supported. Instead, a `HttpStatus` contains a `LocalizedMessage` instance that encapsulates the localization of the status message for use in error templates.

**com.pingidentity.pa.sdk.http.MimeType**

The constants available in this class are now available as constant `MediaType` instances in the class `com.pingidentity.pa.sdk.http.CommonMediaTypes`.

**com.pingidentity.pa.sdk.http.MediaType**

This class is now final and cannot be extended.

Constructing a MediaType**BEFORE:**

```
private void createMediaType(String mediaTypeString)
{
    MediaType mediaType = new MediaType(mediaTypeString);
}
```

**AFTER:**

```
private void createMediaType(String mediaTypeString)
{
    MediaType mediaType = MediaType.parse(mediaTypeString);
}
```

**com.pingidentity.pa.sdk.http.Message**

A number of methods have been removed from the `Message` interface.

Using the Message#getBodyAsStream method**BEFORE:**

```
InputStream bodyStream = message.getBodyAsStream();
```

**AFTER:**

This functionality is no longer supported. However, the following code snippet could be used to maintain semantics of the old method.

```
Body body = message.getBody();
try
{
    body.read();
}
catch (IOException | AccessException e)
{
    throw new RuntimeException("Could not get body as stream",
        e);
}

InputStream bodyStream = body.newInputStream();
```

While this snippet maintains semantics, it is recommended that a plugin propagate errors as an `AccessException` instead of a `RuntimeException`.

*Using the Message#getCharset method*

**BEFORE:**

```
Charset charset = message.getCharset();
```

**AFTER:**

This functionality is no longer supported. However, the following code snippet could be used to maintain semantics of the old method.

```
Charset charset = message.getHeaders().getCharset();
if (charset == null)
{
    charset = StandardCharsets.UTF_8;
}
```

While this snippet maintains semantics, a plugin should consider how to handle the case where a `Charset` is not specified by a `Message`'s header fields. Assuming a `Charset` of UTF-8 could lead to issues in some cases.

*Using the Message#getHeader method*

**BEFORE:**

```
Header header = message.getHeader();
```

**AFTER:**

This functionality is no longer supported. Instead, use `Message#getHeaders` and the `Headers` interface instead of `Header`.

*Using the Message#setHeader method*

**BEFORE:**

```
private void invokeSetHeader(Message message, Header header)
{
    message.setHeader(header);
}
```

**AFTER:**

This functionality is no longer supported. Instead, use `Message#setHeaders` and the `Headers` interface instead of `Header`.

*Using the Message#isDeflate method*

**BEFORE:**

```
boolean deflate = message.isDeflate();
```

**AFTER:**

This method has been removed. However, the value can still be computed with the following code snippet:

```
List<String> contentEncodingValues =
    message.getHeaders().getContentEncoding();
boolean deflate = contentEncodingValues.stream().anyMatch(v ->
    v.equalsIgnoreCase("deflate"))
```

```
&& contentEncodingValues.size() == 1;
```

#### Using the Message#isGzip method

##### **BEFORE:**

```
boolean gzip = message.isGzip();
```

##### **AFTER:**

This method has been removed. However, the value can still be computed with the following code snippet:

```
List<String> contentEncodingValues =
    message.getHeaders().getContentEncoding();
boolean gzip = contentEncodingValues.stream().anyMatch(v ->
    v.equalsIgnoreCase("gzip"))
    && contentEncodingValues.size() == 1;
```

#### Using the Message#isHTTP10 method

##### **BEFORE:**

```
boolean http10 = message.isHTTP10();
```

##### **AFTER:**

This method has been removed. However, the value can still be computed with the following code snippet:

```
boolean http10 = message.getVersion().equals("1.0");
```

#### Using the Message#isHTTP11 method

##### **BEFORE:**

```
boolean http11 = message.isHTTP11();
```

##### **AFTER:**

The method has been removed. However, the value can still be computed with the following code snippet:

```
boolean http11 = message.getVersion().equals("1.1");
```

#### Using the Message#read method

##### **BEFORE:**

```
private void invokeRead(Message message,
                        InputStream inputStream,
                        boolean createBody) throws IOException
{
    message.read(inputStream, createBody);
}
```

##### **AFTER:**

This functionality is no longer supported. A Request attached to an Exchange can no longer be completely replaced, but individual components can be replaced, such as the method, uri, headers and body. A Response attached to an Exchange can be replaced by using `Exchange#setResponse`.

Using the Message#setVersion method**BEFORE:**

```
private void invokeSetVersion(Message message, String version)
{
    message.setVersion(version);
}
```

**AFTER:**

This functionality is no longer supported. The version of a Message cannot be changed.

Using the Message#write method**BEFORE:**

```
private void invokeWrite(Message message,
                        OutputStream output) throws IOException
{
    message.write(output);
}
```

**AFTER:**

This functionality is no longer supported. However, the following code snippet can be used to perform the equivalent operation:

```
private void invokeWrite(Message message,
                        OutputStream output) throws IOException,
                        AccessException
{
    Body body = message.getBody();
    body.read();

    output.write(message.getStartLine().getBytes(StandardCharsets.ISO_8859_1));

    output.write(message.getHeaders().toString().getBytes(StandardCharsets.ISO_8859_1));
    output.write("\r\n".getBytes(StandardCharsets.ISO_8859_1));
    output.write(body.getContent());
    output.flush();
}
```

**com.pingidentity.pa.sdk.http.Method**

The Method interface has been converted to a final class. Additionally, the related Methods enum has been merged into the Method class. The Method class provides common Method instances as class-level constants.

Obtaining a common Method instance**BEFORE:**

```
Method get = Methods.GET
```

**AFTER:**

```
Method get = Method.GET;
```

Using the Method#getMethodName method

**BEFORE:**

```
String methodName = method.getMethodName();
```

**AFTER:**

```
String methodName = method.getName();
```

**com.pingidentity.pa.sdk.http.Request**

A few methods have been removed from the Request interface.

*Using the Request#getPostParams method***BEFORE:**

```
private void invokeGetPostParams(Request request) throws
    IOException
{
    Map<String, String[]> postParams = request.getPostParams();
}
```

**AFTER:**

```
private void invokeGetPostParams(Request request) throws
    AccessException
{
    Body body = request.getBody();
    try
    {
        body.read();
    }
    catch (IOException e)
    {
        throw new AccessException("Failed to read body content",
            HttpStatus.BAD_GATEWAY,
            e);
    }

    Map<String, String[]> postParams = body.parseFormParams();
}
```

*Using the Request#isMultipartFormPost method***BEFORE:**

```
boolean multipartFormPost = request.isMultipartFormPost();
```

**AFTER:**

This method has been removed from the Request interface. However, the value can still be calculated using the following code snippet:

```
Headers headers = request.getHeaders();

boolean multipartFormPost =
    request.getMethod() == Method.POST
    && headers.getContentType() != null
    &&
    headers.getContentType().getBaseType().equals("multipart/form-
data")
```

```
&& headers.getContentType().getParameter("boundary") !=
null;
```

### com.pingidentity.pa.sdk.http.ResponseBuilder

A handful of methods were removed from ResponseBuilder. Additionally, a handful of methods have changed their semantics, particularly those that included an HTML message payload. See the updated JavaDoc for ResponseBuilder for more info.

#### Using the ResponseBuilder#badRequestText method

##### BEFORE:

```
Response response =
    ResponseBuilder.badRequestText(message).build();
```

##### AFTER:

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.BAD_REQUEST)

        .contentType(CommonMediaTypes.TEXT_PLAIN)
          .body(message)
          .build();
```

**NOTE:** This approach does not localize the response body. Using a TemplateRenderer is recommended instead.

#### Using the ResponseBuilder#contentLength method

##### BEFORE:

```
Response response =
    ResponseBuilder.newInstance().contentLength(length).build();
```

##### AFTER:

This functionality is no longer supported. Consider using one of the ResponseBuilder#body methods instead of explicitly setting the content length. This ensures that the body content of the Response aligns with the Content-Length header field.

#### Using the ResponseBuilder#continue100 method

##### BEFORE:

```
Response response = ResponseBuilder.continue100().build();
```

##### AFTER:

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.CONTINUE).build();
```

#### Using the ResponseBuilder#forbiddenText method

##### BEFORE:

```
Response response = ResponseBuilder.forbiddenText().build();
```

##### AFTER:

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.FORBIDDEN)
```

```
.contentType(CommonMediaTypes.TEXT_PLAIN)

.body(HttpStatus.FORBIDDEN.getMessage())
    .build();
```

**NOTE:** This approach does not localize the response body. Using a `TemplateRenderer` is recommended instead.

*Using the `ResponseBuilder#forbiddenWithoutBody` method*

**BEFORE:**

```
Response response =
    ResponseBuilder.forbiddenWithoutBody().build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.FORBIDDEN).build();
```

**BEFORE:**

```
Response response =
    ResponseBuilder.forbiddenWithoutBody(message).build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.FORBIDDEN).build();
```

**NOTE:** In the original method, the `String` message parameter was not used.

*Using the `ResponseBuilder#htmlMessage` method*

**BEFORE:**

```
String message = ResponseBuilder.htmlMessage(caption, text);
```

**AFTER:**

This functionality is no longer supported. Plugins that used this method will need to construct the HTML message without this method. Consider using the `TemplateRenderer` utility class in place of this method.

*Using the `ResponseBuilder#internalServerError` method*

**BEFORE:**

```
Response response =
    ResponseBuilder.internalServerError(message).build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.internalServerError().body(message).build();
```

**NOTE:** This approach does not localize the response body. Using a `TemplateRenderer` is recommended instead.

*Using the `ResponseBuilder#internalServerErrorWithoutBody` method*

**BEFORE:**

```
Response response =
    ResponseBuilder.internalServerErrorWithoutBody().build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.internalServerError().build();
```

Using the ResponseBuilder#newInstance method

The no-arg newInstance method has been removed. A HttpStatus is required to create an instance of ResponseBuilder and the required HttpStatus object should be passed to the newInstance method that accepts a HttpStatus.

**BEFORE:**

```
Response response = ResponseBuilder.newInstance().build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.INTERNAL_SERVER_ERROR).build();
```

Using the ResponseBuilder#noContent method**BEFORE:**

```
Response response = ResponseBuilder.noContent().build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.NO_CONTENT).build();
```

Using the ResponseBuilder#notFoundWithoutBody method**BEFORE:**

```
Response response =
    ResponseBuilder.notFoundWithoutBody().build();
```

**AFTER:**

```
Response response = ResponseBuilder.notFound().build();
```

Using the ResponseBuilder#serverUnavailable method**BEFORE:**

```
Response response =
    ResponseBuilder.serverUnavailable(message).build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.serviceUnavailable().body(message).build();
```

**NOTE:** This approach does not localize the response body. Using a TemplateRenderer is recommended instead.

Using the ResponseBuilder#serviceUnavailableWithoutBody method**BEFORE:**

```
Response response =
    ResponseBuilder.serverUnavailableWithoutBody().build();
```

**AFTER:**

```
Response response = ResponseBuilder.serviceUnavailable().build();
```

Using the ResponseBuilder#status method

The status methods have been removed. Instead the status should be specified to the newInstance method as it is now required.

**BEFORE:**

```
Response response =
    ResponseBuilder.newInstance().status(HttpStatus.OK).build();
```

**AFTER:**

```
Response response =
    ResponseBuilder.newInstance(HttpStatus.OK).build();
```

Using the ResponseBuilder#unauthorizedWithoutBody method**BEFORE:**

```
Response response =
    ResponseBuilder.unauthorizedWithoutBody().build();
```

**AFTER:**

```
Response response = ResponseBuilder.unauthorized().build();
```

**com.pingidentity.pa.sdk.http.Response**

A few methods were removed from the Response interface.

Using the Response#isRedirect method**BEFORE:**

```
boolean redirect = response.isRedirect();
```

**AFTER:**

```
boolean redirect = response.getStatusCode() >= 300
    && response.getStatusCode() < 400;
```

Using the Response#setStatusCode method**BEFORE:**

```
response.setStatusCode(HttpStatus.OK.getCode());
```

**AFTER:**

```
response.setStatus(HttpStatus.OK);
```

*Using the Response#setStatusMessage method*

**BEFORE:**

```
response.setStatusMessage(HttpStatus.OK.getMessage());
```

**AFTER:**

```
response.setStatus(HttpStatus.OK);
```

### **com.pingidentity.pa.sdk.identity**

#### **com.pingidentity.pa.sdk.identity.Identity**

The getTokenExpiration method was updated to use an Instant instead of Date.

*Using the Identity#getTokenExpiration method*

**BEFORE:**

```
Date expiration = identity.getTokenExpiration();
```

**AFTER:**

```
Date expiration = Date.from(identity.getTokenExpiration());
```

#### **com.pingidentity.pa.sdk.identity.OAuthTokenMetadata**

The OAuthTokenMetadata methods now use an Instant instead of a Date.

*Using the OAuthTokenMetadata#getExpiresAt method:*

**BEFORE:**

```
Date expiresAt = metadata.getExpiresAt();
```

**AFTER:**

```
Date expiresAt = Date.from(metadata.getExpiresAt());
```

*Using the OAuthTokenMetadata#getRetrievedAt method:*

**BEFORE:**

```
Date retrievedAt = metadata.getRetrievedAt();
```

**AFTER:**

```
Date retrievedAt = Date.from(metadata.getRetrievedAt());
```

### **com.pingidentity.pa.sdk.identitymapping.header**

ClientCertificateMapping has been removed from the SDK, as it was not required to create an IdentityMappingPlugin implementation.

Plugins utilizing this class should create their own version of this class.

### **com.pingidentity.pa.sdk.policy**

#### **com.pingidentity.pa.sdk.policy.AccessExceptionContext**

The nested Builder class has been removed from `AccessExceptionContext` and instead `AccessExceptionContext` is a builder, that can be initially created with the new `AccessExceptionContext#create` method.

The `LocalizedMessage` interface has been introduced to simplify the configuration of a localized message for use in an error template. A `LocalizedMessage` has three implementations provided in the SDK: `FixedMessage`, `BasicLocalizedMessage` and `ParameterizedLocalizedMessage`. See the following code examples for more information on using these new classes.

*Constructing an AccessExceptionContext:*

**BEFORE:**

```
private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,
        Throwable cause)
{
    return AccessExceptionContext.builder()
        .cause(cause)
        .httpStatus(httpStatus)
        .exceptionMessage(httpStatus.getMessage())
        .errorDescription(httpStatus.getLocalizationKey())
            .errorDescriptionIsKey(true)
        .errorDescriptionSubstitutions(new String[0])
            .build();
}
```

**AFTER:**

```
private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,
        Throwable cause)
{
    return AccessExceptionContext.create(httpStatus)
        .cause(cause)
        .exceptionMessage(httpStatus.getMessage())
        .errorDescription(httpStatus.getLocalizedMessage());
}
```

**BEFORE:**

```
private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,
        String localizationKey,
        String[] substitutions)
{
    return AccessExceptionContext.builder()
        .httpStatus(httpStatus)
        .errorDescription(localizationKey)
            .errorDescriptionIsKey(true)
```

```

        .errorDescriptionSubstitutions(substitutions)
            .build();
    }

```

**AFTER:**

```

private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,

    String localizationKey,

    String[] substitutions)
{
    LocalizedMessage localizedMessage =
        new ParameterizedLocalizedMessage(localizationKey,
        substitutions);

    return AccessExceptionContext.create(httpStatus)

    .errorDescription(localizedMessage);
}

```

**BEFORE:**

```

private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,

    String localizationKey)
{
    return AccessExceptionContext.builder()
        .httpStatus(httpStatus)

    .errorDescription(localizationKey)
        .errorDescriptionIsKey(true)
        .build();
}

```

**AFTER:**

```

private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus,

    String localizationKey)
{
    LocalizedMessage localizedMessage = new
    BasicLocalizedMessage(localizationKey);
    return AccessExceptionContext.create(httpStatus)

    .errorDescription(localizedMessage);
}

```

**BEFORE:**

```

private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus)
{
    return AccessExceptionContext.builder()
        .from(httpStatus)

    .httpStatusDescription(httpStatus.getLocalizationKey())
}

```

```

        .HttpStatusDescriptionIsKey(true)
        .templateFile("template.html")
        .contentType("text/html");
    }

```

**AFTER:**

```

private AccessExceptionContext
    createAccessExceptionContext(HttpStatus httpStatus)
{
    return AccessExceptionContext.create(httpStatus)

    .errorDescription(httpStatus.getLocalizedMessage());
}

```

**NOTE:** this example demonstrates that it is no longer possible to set a template file and its associated content type on an `AccessExceptionContext`. To generate an error response from a template file, use the `TemplateRenderer` class. See the JavaDoc for the `TemplateRenderer` class for more information.

**com.pingidentity.pa.sdk.policy.AccessException**

The changes to `AccessExceptionContext` apply to the creation of `AccessException` because the creation of an `AccessException` requires an `AccessExceptionContext`.

In addition to these changes, obtaining information from `AccessException` has also changed. See the code examples below for more information.

Finally, `AccessException` no longer derives from `IOException` and derives directly from `Exception` instead.

Constructing an AccessException:**BEFORE:**

```

private void throwAccessException(String errorDescription,
                                 Throwable throwable) throws
    AccessException
{
    throw new AccessException(errorDescription, throwable);
}

```

**AFTER:**

```

private void throwAccessException(String errorDescription,
                                 Throwable throwable) throws
    AccessException
{
    LocalizedMessage templateMessage = new
    FixedMessage(errorDescription);
    throw new
    AccessException(AccessExceptionContext.create(HttpStatus.INTERNAL_SERVER_ERROR)

    .exceptionMessage(errorDescription)

    .cause(throwable)

    .errorDescription(templateMessage));
}

```

**BEFORE:**

```
private void throwAccessException(String errorDescription) throws
    AccessException
{
    throw new AccessException(errorDescription);
}
```

**AFTER:**

```
private void throwAccessException(String errorDescription) throws
    AccessException
{
    LocalizedMessage templateMessage = new
    FixedMessage(errorDescription);
    throw new
    AccessException(AccessExceptionContext.create(HttpStatus.INTERNAL_SERVER_ERROR)
    .exceptionMessage(errorDescription)
    .errorDescription(templateMessage));
}
```

**BEFORE:**

```
private void createAccessException(int statusCode,
    String statusMessage,
    String errorDescription)
    throws AccessException
{
    throw new AccessException(statusCode, statusMessage,
    errorDescription);
}
```

**AFTER:**

```
private void createAccessException(int statusCode,
    String statusMessage,
    String errorDescription)
    throws AccessException
{
    HttpStatus httpStatus = new HttpStatus(statusCode,
    statusMessage);
    LocalizedMessage templateMessage = new
    FixedMessage(errorDescription);
    throw new
    AccessException(AccessExceptionContext.create(httpStatus)
    .exceptionMessage(errorDescription)
    .errorDescription(templateMessage));
}
```

**BEFORE:**

```
private void throwAccessException(int statusCode,
    String statusMessage,
    String errorDescription,
    Throwable throwable) throws
    AccessException
{
```

```

        throw new AccessException(statusCode, statusMessage,
            errorDescription, throwable);
    }

```

**AFTER:**

```

private void throwAccessException(int statusCode,
                                String statusMessage,
                                String errorDescription,
                                Throwable throwable) throws
    AccessException
{
    HttpStatus httpStatus = new HttpStatus(statusCode,
        statusMessage);
    LocalizedMessage templateMessage = new
        FixedMessage(errorDescription);
    throw new
        AccessException(AccessExceptionContext.create(httpStatus)

        .exceptionMessage(errorDescription)

        .errorDescription(templateMessage)

        .cause(throwable));
}

```

**BEFORE:**

```

private void throwAccessException() throws AccessException
{
    throw new AccessException(AccessExceptionContext.builder()

        .httpStatusCode(403)

        .httpStatusMessage("Forbidden")

        .build());
}

```

**AFTER:**

```

private void throwAccessException() throws AccessException
{
    throw new
        AccessException(AccessExceptionContext.create(HttpStatus.FORBIDDEN));
}

```

*Using the AccessException#getExceptionContext method***BEFORE:**

```

AccessExceptionContext context =
    accessException.getExceptionContext();

```

**AFTER:**

This functionality is no longer supported. The information that used to be provided by the `AccessExceptionContext` is now provided directly by an `AccessException`.

*Using the AccessException#getHttpStatusCode method*

**BEFORE:**

```
int statusCode = accessException.getStatusCode();
```

**AFTER:**

```
int statusCode = accessException.getErrorStatus().getCode();
```

Using the `AccessException#getHttpStatusMessage` method**BEFORE:**

```
String statusMessage = accessException.getHttpStatusMessage();
```

**AFTER:**

```
String statusMessage =
    accessException.getErrorStatus().getMessage();
```

Using the `AccessException#setHttpStatusCode` method**BEFORE:**

```
accessException.setHttpStatusCode(statusCode);
```

**AFTER:**

This functionality is no longer supported. The status code associated with an `AccessException` is fixed once it is constructed.

Using the `AccessException#setHttpStatusMessage` method**BEFORE:**

```
accessException.setHttpStatusMessage(statusMessage);
```

**AFTER:**

This functionality is no longer supported. The status message associated with an `AccessException` is fixed once it is constructed.

**com.pingidentity.pa.sdk.policy.RuleInterceptor**

The `handleRequest` and `handleResponse` methods on a `RuleInterceptor` no longer throw an `IOException`. Instead, they throw an `AccessException`, which no longer derives from `IOException`.

Accounting for the `RuleInterceptor#handleRequest` method signature change**BEFORE:**

```
@Override
public Outcome handleRequest(Exchange exchange) throws
    IOException
{
    Outcome outcome = applyPolicy(exchange);

    return outcome;
}
```

**AFTER:**

```
@Override
```

```
public Outcome handleRequest(Exchange exchange) throws
    AccessException
{
    Outcome outcome = applyPolicy(exchange);

    return outcome;
}
```

*Account for the RuleInterceptor#handleResponse method signature change*

**BEFORE:**

```
@Override
public void handleResponse(Exchange exchange) throws IOException
{
    applyPolicyToResponse(exchange.getResponse());
}
```

**AFTER:**

```
@Override
public void handleResponse(Exchange exchange) throws
    AccessException
{
    applyPolicyToResponse(exchange.getResponse());
}
```

**com.pingidentity.pa.sdk.policy.error.InternalServerErrorCallback**

This class has been removed. Use LocalizedInternalServerErrorCallback instead.

**com.pingidentity.pa.sdk.services**

**com.pingidentity.pa.sdk.services.ServiceFactory**

This class is now final and cannot be extended.

**com.pingidentity.pa.sdk.siteauthenticator**

**com.pingidentity.pa.sdk.siteauthenticator.SiteAuthenticatorInterceptor**

This interface is no longer a RequestInterceptor or ResponseInterceptor, but it still defines the handleRequest and handleResponse methods:

```
public interface SiteAuthenticatorInterceptor<T extends
    PluginConfiguration>
    extends DescribesUIConfigurable, ConfigurablePlugin<T>
{
    void handleRequest(Exchange exchange) throws AccessException;
    void handleResponse(Exchange exchange) throws
        AccessException;
}
```

Additionally, these methods now only throw an AccessException instead of an IOException or InterruptedException.

*Accounting for the SiteAuthenticatorInterceptor#handleRequest method signature change*

**BEFORE:**

```
@Override
public Outcome handleRequest(Exchange exc)
    throws RuntimeException, IOException,
    InterruptedException
{
    // Site authenticator implementation //

    return Outcome.CONTINUE;
}
```

**AFTER:**

```
@Override
public void handleRequest(Exchange exc) throws AccessException
{
    // Site authenticator implementation //
}
```

*Accounting for the SiteAuthenticatorInterceptor#handleResponse method signature change***BEFORE:**

```
@Override
public void handleResponse(Exchange exc) throws IOException
{
    // Site authenticator response implementation //
}
```

**AFTER:**

```
@Override
public void handleResponse(Exchange exc) throws AccessException
{
    // Site authenticator response implementation //
}
```

**com.pingidentity.pa.sdk.ui****com.pingidentity.pa.sdk.ui.ConfigurationType**

The deprecated PRIVATEKEY enum value has been removed. Instead use a ConfigurationType of ConfigurationType#SELECT and specify the PrivateKeyAccessor.class instance to ConfigurationBuilder#dynamicOptions or UIElement#modelAccessor.

**com.pingidentity.pa.sdk.user****com.pingidentity.pa.sdk.user.User**

This class has been removed from the SDK. Use the Identity interface instead. An instance of Identity can be retrieved from the Exchange, similar to the User interface.

**com.pingidentity.pa.sdk.util****com.pingidentity.pa.sdk.util.TemplateRenderer**

The semantics of the renderResponse method have changed so it produces a Response and does not have any side-effects on the specified parameters.

Using the `TemplateRenderer#renderResponse` method:

**BEFORE:**

```
private void invokeRenderResponse(TemplateRenderer
    templateRenderer,
                                Map<String, String> context,
                                String templateName,
                                Exchange exchange,
                                ResponseBuilder builder)
{
    templateRenderer.renderResponse(context, templateName,
    exchange, builder);
}
```

**AFTER:**

```
private void invokeRenderResponse(TemplateRenderer
    templateRenderer,
                                Map<String, String> context,
                                String templateName,
                                Exchange exchange,
                                ResponseBuilder builder)
{
    Response response = templateRenderer.renderResponse(exchange,
    context,
    templateName,
    builder);
    exchange.setResponse(response);
}
```

## Protect a web-based application using PingFederate and PingAccess in a proxy deployment

---

### Protect a web-based application in a proxy deployment

This document describes the basic steps necessary to protect a web-based application using the combination of **PingAccess** as the access manager and **PingFederate** as the token provider.

Along with a description of the configuration steps that are required, this document includes a functioning example using the **PingAccess QuickStart** application. You can perform the example configuration to achieve a working result and become familiar with this solution, or you can substitute your own data.

Note that this is a basic configuration featuring:

- a PingFederate HTML Form Adapter with an instance of a Simple Password Credential Validator
- the PingFederate Access Token Manager (ATM) using the Internally Managed Reference Token data model

Your configuration may call for additional settings and components to satisfy network and/or security requirements. Links to additional resources that explain these additional settings and components are offered throughout this document.

This document does not detail the usage of identity mappings or authentication requirements that are common components of a typical configuration. As these components are simple to configure and beyond the scope of this document, you can read more about them and other features in the [PingAccess User Interface Reference Guide](#).

#### Prerequisites

To complete the example configuration, the following prerequisites should be satisfied:

1. You have downloaded and performed a basic installation of [PingAccess 5.1](#) and [PingFederate 9.1](#).
2. You have downloaded the [PingAccess QuickStart \(Login required\)](#) application, unzipped the file, and copied the `\pingaccess-quickstart-5.1.0\pf-dist\PingAccessQuickStart.war` file to `\Program Files\Ping Identity\pingfederate-9.1.0\pingfederate\server\default\deploy`.
3. The PingAccess QuickStart application is hosted and available at `https://mypingfedserver:9031/PingAccessQuickStart`.

To begin, [Configure PingFederate for PingAccess connectivity](#) on page 396.

## Configure PingFederate for PingAccess connectivity

This document provides the sequence of steps for configuring PingFederate components for PingAccess connectivity as required for this solution. In this configuration procedure, you will:

1. [Enable PingFederate roles and protocols](#) on page 396
2. [Create a password credential validator](#) on page 396
3. [Configure an IdP adapter](#) on page 397
4. [Define the scope](#) on page 397
5. [Create an access token manager](#) on page 398
6. [Configure an IdP adapter mapping](#) on page 398
7. [Configure an access token mapping](#) on page 398
8. [Create an OpenID Connect policy](#) on page 398
9. [Create a resource server client](#) on page 399
10. [Create a web session client](#) on page 399
11. [Create and export a certificate](#) on page 400

### Important:

1. These steps assume you have installed PingFederate. The example assumes that your PingFederate instance is available at `https://mypingfedserver`, using ports 9031 and 9999 respectively for the runtime and administration functions.
2. These steps assume you have installed PingAccess. This example assumes that your PingAccess instance is available at `https://mypingaccessserver` and that 3000 is the default listening port.

### Enable PingFederate roles and protocols

Ensure that PingFederate is configured to respond to OAuth and OIDC requests using the following steps. For more information on PingFederate Roles and Protocols, see [Choose roles and protocols](#).

1. Navigate to **Server Configuration > System Settings > Server Settings**.
2. Click **Roles & Protocols** and ensure the following items are selected:
  - **OAuth** (role) and **OpenID Connect** (protocol)
  - **IdP** (role) and **SAML 2.0** (protocol)
3. On the **Federation Info** screen, enter the URL of your PingFederate environment and your SAML 2.0 entity ID. For example:
  - **My Base URL:** `https://mypingfedserver:9031`
  - **SAML 2.0 Entity ID:** `https://mypingfedserver/idp`
4. Click **Save**.

### Create a password credential validator

Create a password credential validator, then create a username and password to authenticate with. For more information on Password Credential Validators, see [Manage password credential validators](#).

1. Navigate to **Settings > Server Configuration > Authentication > Password Credential Validators**.
2. Click **Create New Instance**.
3. Specify an **Instance Name** and **Instance ID** of your choosing. For example:

```
Instance Name: My_PCV
Instance ID: mypcv
```

4. In the **Type** list, select **Simple Username Password Credential Validator**.
5. On the **Instance Configuration** page, click **Add a new row to 'Users'**.
6. Create a **Username**, then create and confirm a **Password**.
7. Click **Update**.
8. On the **Summary** page, click **Done**.
9. Click **Save**.

### Configure an IdP adapter

Configure an IdP adapter to look up session information and provide user identification to PingFederate. This example uses an instance of the HTML Form Adapter with an instance of the Simple Password Credential Validator. For more information, see [Manage IdP adapters](#).

1. Navigate to **Identity Provider > Application Integration > Adapters**.
2. Click **Create New Instance**.
3. Specify an **Instance Name** and **Instance ID** of your choosing. For example:

```
Instance Name: My_IdP
Instance ID: myidp
```

4. In the **Type** list, select **HTML Form IdP Adapter**.
5. On the **IdP Adapter** page, click **Add a new row to 'Credential Validators'**.
6. In the **Password Credential Validator Instance** list, select the password credential validator you created (*Example: My\_PCV*) and click **Update**.
7. On the **Adapter Attributes** page, next to the `username` attribute, click to select the **Pseudonym** checkbox
8. On the **Summary** page, click **Done**.
9. Click **Save**.

### Define the scope

Use the Scope Management screen to define the default scope. For more information, see [Define scopes](#).

1. Navigate to **OAuth Server > Authorization Server > Scope Management**.
2. On the **Common Scopes** page, enter the following scope values and their descriptions one at a time, clicking **Add** with each entry:

Scope Value	Scope Description
address	address
email	email
openid	openid
phone	phone
profile	profile

3. On the **Default Scope** page, enter a description, for example: `default scope`.
4. Click **Save**.

### Create an access token manager

Create an access token that is used to grant access and control access parameters. This sample configuration uses an instance of the Access Token Manager (ATM) using the Internally Managed Reference Tokens data model. For more information, see [OAuth access token management](#).

1. Navigate to **OAuth Server > Token Mapping > Access Token Management**.
2. Click **Create New Instance**.
3. Specify an **Instance Name** and **Instance ID** of your choosing. For example:

```
Instance Name: General Access Token
Instance ID: GeneralAccessToken
```

4. In the **Type** list, select **Internally Managed Reference Tokens**.
5. On the **Access Token Attribute Contract** page, in the **Extend the Contract** field, enter `UserName` and click **Add**.
6. On the **Summary** page, click **Save**.

### Configure an IdP adapter mapping

Configure an IdP adapter mapping to map attributes. For more information, see [Manage IdP adapter mappings for OAuth](#).

1. Navigate to **OAuth Server > Grant Mapping > IdP Adapter Mapping**.
2. In the **Source Adapter Instance** list, select the adapter you created.
3. Click **Add Mapping**.
4. On the **Contract Fulfillment** page, in the **Source** lists, select **Adapter** for both `USER_KEY` and `USER_NAME`.
5. In the **Value** lists, select `username` for both items.
6. On the **Summary** page, click **Save**.

### Configure an access token mapping

Configure an access token mapping to map attributes to be requested from the OAuth resource server with the access token. For more information, see [Manage access token mappings](#).

1. Navigate to **OAuth Server > Token Mapping > Access Token Mapping**.
2. In the **Context** list, select `Default` or select your IdP adapter instance.
3. In the **Access Token Manager** list, select the access token you created. For example:

```
GeneralAccessToken
```

4. Click **Add Mapping**.
5. On the **Contract Fulfillment** page, in the **Source** list, select `Persistent Grant`.
6. In the **Value** list, select `USER_KEY`.
7. On the **Summary** page, click **Save**.

### Create an OpenID Connect policy

Configure an OpenID Connect policy so you can define OpenID Connect policies for client access to attributes mapped according to OpenID specifications. For more information, see [Configure OpenID Connect policies](#).

1. Navigate to **OAuth Server > Token Mapping > OpenID Connect Policy Management**.
2. Click **Add Policy**.
3. Specify a **Policy ID**, for example: `OIDC`
4. Specify a **Name**, for example: `OIDC`

5. In the **Access Token Manager** list, select the access token you created. For example:

```
GeneralAccessToken
```

6. On the **Attribute Contract** page, delete all items beneath **Extend the Contract**.
7. On the **Contract Fulfillment** page, in the **Source** list, select `Access Token`.
8. In the **Value** list, select `UserName`.
9. On the **Summary** page, click **Done**.
10. Click **Save**.
11. Beside the policy you created, click **Set as Default**.
12. Click **Save**.

### Create a resource server client

Configure an OAuth client for use with PingFederate token provider resource server configuration in PingAccess. For more information, see [Manage OAuth clients](#).

1. Navigate to **OAuth Server > Clients > Manage All**.
2. Click **Add Client**.
3. Specify a **Client ID**. For example:

```
pa_rs
```

4. Specify a **Name**. For example:

```
PingAccessResourceServer
```

5. Select **Client Secret**.
6. Generate a secret by clicking **Generate Secret**. Copy this secret to a secure location so that you can use it in PingAccess configuration.
7. In the **Redirect URIs** field, add the OIDC callback redirect to the PingAccess server. For example:

```
https://mypingaccessserver:3000/pa/oidc/cb
```

8. Click **Add**.
9. For the **Allowed Grant Type** setting, select the **Access Token Validation (Client is a Resource Server)** check box.
10. Click **Save**.
11. Click **Save**.

### Create a web session client

Configure an OAuth client for use with web session configuration in PingAccess. For more information, see [Manage OAuth clients](#).

1. Navigate to **OAuth Server > Clients > Manage All**.
2. Click **Add Client**.
3. Specify a **Client ID**, for example:

```
pa_wam
```

4. Specify a **Name**. For example:

```
PingAccessWebAccessManagement
```

5. Select **Client Secret**.
6. Generate a secret by clicking **Generate Secret**. Copy this secret to a secure location so that you can use it in PingAccess configuration.

7. In the **Redirect URIs** field, add the OIDC callback redirect to the PingAccess server, for example:

```
https://mypingaccessserver:3000/pa/oidc/cb
```

8. Click **Add**.

9. Select the **Bypass Authorization Approval** check box.

10. For the **Allowed Grant Type** setting, select the **Authorization Code** check box.

11. Click **Save**.

12. Click **Save**.

### Create and export a certificate

Create and export a certificate for the PingFederate server that you will import to PingAccess to establish trust. For more information, see [Manage SSL server certificates](#).

1. Navigate to **Server Configuration > Certificate Management > SSL Server Certificates**
2. Click **Create New**.
3. In the **Common Name** field, enter the PingFederate server address. For example:

```
mypingfedserver
```

4. Complete the remaining fields as required.
5. Click **Next**
6. Click **Done**.
7. Under the **Action** heading, click **Activate for Runtime Server**.
8. **Export** the certificate only.
9. Click **Save**.

Next, [Connect to PingFederate and configure an application in PingAccess](#) on page 400.

## Connect to PingFederate and configure an application in PingAccess

This document provides the sequence of steps for configuring the PingAccess components required for this solution. In this configuration procedure, you will:

1. [Import certificates and create a trusted certificate group](#) on page 400
2. [Configure the token provider](#) on page 401
3. [Create a web session](#) on page 401
4. [Create a virtual host](#) on page 402
5. [Create a site](#) on page 402
6. [Create an application](#) on page 402

**Important:** The examples in this procedure assume that the PingAccess QuickStart application is available at the following address:

```
https://mypingfedserver:9031/PingAccessQuickStart
```

### Import certificates and create a trusted certificate group

Import a certificate for the PingFederate server to establish trust. For more information, see [Certificates](#).

1. Navigate to **Settings > Security > Certificates**.
2. Click **+** to the right of the **Certificates** subheading.
3. Enter an **Alias** for the certificate. For example:

```
PingFed
```

4. Click **Choose File** to select the certificate.

5. Click **Add** to import the certificate. A new certificate row appears on the Certificates page.
6. Click **+** to the right of the **Trusted Certificate Groups** heading.
7. Drag a certificate onto the box that appears.
8. Enter a **Name** for the group in the box that appears. For example:

```
PingFed
```

9. Click **Add**.

### Configure the token provider

Establish communication with the token provider, PingFederate. For more information, see [Manage Token Provider](#).

1. Navigate to **Settings > System > Token Provider > Runtime**.
2. Enter the **Host** name or IP address for the PingFederate Runtime. For example:

```
mypingfedserver
```

3. Enter the **Port** number for PingFederate Runtime. For example:

```
9031
```

4. Select **Secure**.
5. From the **Trusted Certificate Group** list, select the `PingFed` certificate group.
6. Click **Save**.
7. Navigate to **Settings > System > Token Provider > Administration**.
8. Enter the **Host** name or IP address for access to the PingFederate Administrative API. For example:

```
mypingfedserver
```

9. Enter the **Port** number for access to the PingFederate Administrative API. For example:

```
9999
```

10. Enter the PingFederate **Admin Username**.
11. Enter the **Admin Password**.
12. Select **Secure**.
13. From the **Trusted Certificate Group** list, select the `PingFed` certificate group.
14. Click **Save**.
15. Navigate to **Settings > System > Token Provider > OAuth Resource Server**
16. Enter the OAuth **Client ID** you defined when creating the PingAccess OAuth client in PingFederate. For example:

```
pa_rs
```

17. Enter the **Client Secret** you defined when creating the PingAccess OAuth client within PingFederate.
18. In the **Subject Attribute Name** field, enter the attribute you want to use from the OAuth access token as the subject for auditing purposes. For example:

```
username
```

19. Click **Save**.

### Create a web session

Create a web session to control access. For more information, see [Web Sessions](#).

1. Navigate to **Settings > Access > Web Sessions**

2. On the Web Session page, click **Add Web Session**.
3. Enter a unique **Name** for the web session, up to 64 characters, including special characters and spaces. For example:

```
PF_WAM
```

4. Select `Encrypted JWT` for **Cookie Type**.
5. Specify the **Audience** that the PA Token is applicable to, represented as a short, unique identifier between 1 and 32 characters. For example:

```
global
```

6. Specify the **OpenID Connect Login Type** `CODE`.
7. Specify the **Client ID**. For example:

```
pa_wam
```

8. Specify the **Client Secret**
9. Click **Save**.

### Create a virtual host

Create a virtual host that PingAccess will respond to. For more information, see [Virtual Hosts](#).

1. Navigate to **Settings > Access > Virtual Hosts**.
2. Click **Add Virtual Host**.
3. Enter the **Host** name for the Virtual Host. For example:

```
mypingaccessserver
```

4. Enter the **Port** number for the Virtual Host. For example:

```
3000
```

5. Click **Save**.

### Create a site

Create a site to define the location of the application that PingAccess is protecting. For more information, see [Sites](#).

1. Navigate to **Main > Sites > Sites**.
2. Click **Add Site**.
3. Specify a **Name**. For example:

```
QuickStart
```

4. Specify the **Target**. The format for this is `hostname:port`. For example:

```
mypingfedserver:9031
```

5. Select **Secure** and choose the PingFed **Trusted Certificate Group**.
6. Click **Save**.

**Note:** If the target site cannot be contacted, the site is saved and a warning is displayed indicating the reason the site was not reachable.

### Create an application

Create an application to define the resource that PingAccess is protecting. For more information, see [Applications](#).

1. Navigate to **Main > Applications**.
2. Click **Add Application**.
3. Provide a unique name for the application. For example:

```
QuickStart
```

4. Specify the context at which the application is accessed at the site. For example:

```
/PingAccessQuickStart
```

5. Specify the virtual host for the application. For example:

```
mypingaccessserver:3000
```

6. Specify the application type `web` and select the **Web Session** for the application. For example:

```
PF_WAM
```

7. Specify the application destination type `Site` and select the **Site** requests are sent to when access is granted. For example:

```
PingAccessQuickStart
```

8. Select the **Require HTTPS** option.
9. Select the **Enabled** checkbox.
10. Click **Save**.

## Test the configuration

To test the solution after configuration is complete:

1. Open your browser.
2. Navigate to the application using a combination of the Virtual Host and Context Root that you defined in PingAccess. For example:

```
https://mypingaccessserver:3000/PingAccessQuickStart
```

3. Login using the credentials you created for the PingFederate [password credential validator](#).

## Protect applications using PingAccess and PingOne for Customers

---

### Solution overview

This document provides the steps required to configure PingAccess as part of the use case to provide secure external access to applications using PingAccess and PingOne for Customers. In this scenario, PingAccess provides an external path to applications while PingOne for Customers acts as the token provider for associated sessions.

This solution requires you to perform the following tasks. For more information about the requirements and options available for each task, review the task.

- [Configure PingAccess to use PingOne for Customers as the token provider](#)
- [Configure a PingAccess application](#) for each application you want to protect and make available as part of this solution. Applications may require configuration of:
  - A virtual host
  - A web session or access token validator
  - A site
  - An application

When the configuration is complete, you can test the application using the **Virtual Host** and **Context Root** that you assign to it in PingAccess.

## Configure PingAccess to use PingOne for Customers as the token provider

**Tip:** For more information on configuring the token provider, see [Configure a token provider](#).

### Assumptions

- You have installed PingAccess and can access the [Administrative console](#). For information on installing PingAccess, see [Install PingAccess](#).

**Note:** The default credential set should be changed upon first usage. The default credentials for your PingAccess installation are:

```
Username: Administrator
Password: 2Access
```

- You have [configured an application](#) in PingOne for Customers.

### Configure the token provider

- Navigate to **Settings > System > Token Provider**.
- Select the **PingOne** token provider type.
- In the **Issuer** field, enter the PingOne for Customers **Issuer** URL. To obtain the Issuer URL from PingOne for Customers, in PingOne for Customers, navigate to the **Configuration** tab of an application and copy the **Issuer** value.
- Provide a **Description** of the token provider.
- In the **Trusted Certificate Group** list, select **Java Trust Store** or **Trust Any**.
- Click **Save**.

## Configure a PingAccess application

This document describes the steps required to configure PingAccess applications. Use these instructions for each application that you want to configure.

### Assumptions:

- You have installed PingAccess and can access the [Administrative console](#). For information on installing PingAccess, see [Install PingAccess](#).

**Note:** The default credential set should be changed upon first usage. The default credentials for your PingAccess installation are:

```
Username: Administrator
Password: 2Access
```

- You have [configured an application](#) in PingOne for Customers.
- PingAccess is [configured](#) to use PingOne for Customers as the token provider.

### Create a virtual host

**Tip:** For more information on creating a virtual host, see [Create a virtual host](#).

- Navigate to **Settings > Access > Virtual Hosts**.
- Click **Add Virtual Host**.
- In the **Host** field, enter the Host name you want to use for the Virtual Host.
- In the **Port** field, enter the port number you want to use for this virtual host..
- Click **Save**.

### Create a web session

**Tip:** For more information on creating a web session, see [Create a web session](#).

**Note:** A web session is only used when protecting a web application. To protect APIs, you will configure an Access Token Validator.

1. Navigate to **Settings > Access > Web Sessions**.
2. Click **Add Web Session**.
3. Provide a **Name** for the web session.
4. Select the **Cookie Type**, either **Signed JWT** or **Encrypted JWT**.
5. Provide a unique value for the **Audience**.
6. In the **Client ID** field, enter the PingOne for Customers **Client ID**. The Client ID can be found on the **Profile** tab of the application you created.
7. In the **Client Secret** field, enter the **Client Secret** found on the application's **Configuration** tab.
8. Ensure the **Scopes** you specify match those configured for the PingOne for Customers application. Scopes are found on the **Access** tab of your PingOne for Customers application.
9. Click **Save**.

### Create a site

**Tip:** For more information on creating a site, see [Manage Sites](#).

**Note:** In some configurations, it is possible that a site may contain more than one application. A site can be used with more than one application, where appropriate.

1. Navigate to **Main > Sites > Sites**.
2. Click **Add Site**.
3. Specify a **Name** for the site.
4. Enter the site **Target**. The target is the hostname:port pair for the server hosting the application. Do not enter the path for the application in this field. For example, an application at `https://mysite:9999/AppName` will have a target value of `mysite:9999`.
5. Indicate whether or not the target is expecting **Secure** connections.
6. If the target is expecting secure connections, set the **Trusted Certificate Group to Trust Any**.
7. Click **Save**.

### Create an application

You will create an application in PingAccess for each application that you want to protect.

**Tip:** For more information on creating an application, see [Manage Applications](#).

1. Navigate to **Main > Applications**.
2. Click **Add Application**.
3. Specify a **Name** for the application.
4. Optionally, enter a **Description** for the application.
5. Specify the **Context Root** for the application. For example, an application at `https://mysite:9999/AppName` will have a context root of `/AppName`. If the application is on the root of the server, you can set the context root as `/`. The context root must begin with a slash (`/`), must not end with a slash (`/`), and can be more than one layer deep, for example, `/Apps/MyApp`.
6. Select the **Virtual Host** you created.

**Note:** The combination of Virtual Host and Context Root must be unique in PingAccess.

7. Specify **Application Type of Web**.
8. Select the **Web Session** you created.
9. Select the **Site** you created that contains the application.
10. Select **Enabled** to enable the site when you save.
11. Click **Save**.

# Migrating Access Management Infrastructure to PingAccess

---

## Introduction

---

Choose from one of the following topics:

- [About PingAccess Policy Migration \(PAPM\)](#) on page 406
- [Platform architecture](#) on page 406
- [PAPM naming process](#) on page 408

## About PingAccess Policy Migration (PAPM)

PingAccess Policy Migration simplifies Access Management infrastructure migration from CA SSO (SiteMinder) and Oracle Access Manager (OAM) to PingAccess. PAPM enables the easy migration of policy and configuration from the existing system to PingAccess, allowing for easier configuration of PingAccess applications and policies while keeping existing policy behavior.

## Platform architecture

An embedded Jetty server powers the PAPM platform. The applications found in the User Interface leverage a local database. It features:

- **Single Deployment Directory:** All deployment code and the included database are packaged in a single directory. This enables a simple deployment package and reusable configurations.
- **Login Flexibility:** Login to the PAPM platform is available via a file-based login or external LDAP with group-based authorization.
- **Backup:** PAPM is not designed to be highly available. The database is regularly archived in a local backup folder. However the database should be periodically backed up onto another server for disaster recovery.

**Note:** PAPM requires API access to the PingAccess and PingFederate Admin API consoles for EVERY available environment

## Automating policy management

Successful policy automation begins with policy creation. The PAPM methodology builds policies that are secure, portable, flexible, and well named with policy automation.

### Policy Management Lifecycle

Before embarking on a large-scale policy management project, it is important to understand the lifecycle of a Ping Policy and the issues that limit successful operationalization and automation:

1. **Build** - The policy lifecycle starts with creating application policies. This is the most critical stage of policy development and often the predecessor to an automation program's success or failure.
2. **Test** - New policies test for logic, SSO integration, and performance. The applications protected by PingAccess policies deploy on the network in production before they are tested. This creates an unnecessary linkage between the SSO, operations, and application teams. In production, debugging activities are limited to late night downtime that SSO teams must accommodate to execute policy validation.
3. **Refine** - Correcting issues discovered during policy testing typically requires a policy change.
4. **Promote (and Policy Promotion Process)** - Once a policy is tested and ready for implementation, it promotes to a production environment. PAPM automates the Policy Migration Process for reliable / error free migrations. It reduces the pitfalls that can occur when the administrator manually inputs policy data for policy migration.

PingAccess and PingFederate leverage APIs to export and import policy data for migration. However, they do not support the changes for multiple environments or for singular application policies. For example, the virtual hostname for an application in Dev (e.g. app-dev.company.com) will always be different than the virtual hostname in production (e.g. app.company.com). Automation requires any environment-related mutable data be managed. It is also critical to migrate data changes and any shared secrets that PingAccess and PingFederate are unable to export.

#### The Policy Promotion Process

- **1. Package(Export):** Export an application policy and all of its dependencies. This package is stored in the H2 database.
- **2. Transform:** Change all environment dependent data to the target environment. (E.g. map from dev.company.com to sit.company.com).
- **3. Backup:** Prior to importing the new policy, create a backup of the existing application policy and all of its dependencies.
- **4. Remove:** Remove the existing application policy and its dependencies.
- **5. Import:** Create a new application from the transformed export.
  - **If Error, Recover:** Use the backup to recover from any errors.
- **6. Activate:** Once the policy is pushed in PingAccess, it becomes active. The push to PingFederate must be separately pushed to the cluster. The PAPM will automatically call the API to push to the cluster and fully activate the application policy.

**Note:** It is also possible to merge and link application policies instead of the simpler approach of remove and replace. An organization should standardize its approach for consistent policy management.

- 5. Remove** - Administrators are required to remove unwanted Ping policies meticulously in the reverse order created. Removing a top-level application policy also disconnects the links to policy objects (which may lead to policy orphans).
- 6. Recover** - While no change is risk-free, the ability to recover policy information from a backup or previous version is helpful. Because the PingAccess Admin stores policy data in a flat-file database, it is impossible to recover individual copies of application policies.

## PAPM naming process

Administrators may find themselves creating poorly named policies that lack scalability and portability in an attempt to maintain legacy naming conventions or policy configurations. An administrator can choose to name policy objects without restraint or adherence to these standards. Reused policy objects can lead to a number of issues, such as accidentally changing a cross-dependent policy object with unintentional impacts to an application.

### Standardized names

With standardized names, it is easy to identify the links between an application policy, the HTTP headers it outputs, the web session, the OIDC policy and OIDC client just by looking at the name, even when the policy is in both PingAccess and PingFederate. Naming standards replace the effort it takes to manually setup these relationships using both PingAccess and PingFederate.

### Naming a policy

Policy objects are built using the application policy name (e.g. "MyTestPolicy" or "AppName" as shown in diagram). Policy objects are immediately recognizable via their name. This is also important when cleaning up policy object orphans that link to an application policy. This naming structure is baked into PAPM.

## Naming a Policy

## PingAccess Policy Migration

---

PingAccess Policy Migration (PAPM) v1.0 delivers the following:

- [Settings](#) on page 409
- [Policy Migration for CA SSO \(SiteMinder\)](#) on page 409
- [Policy Migration for Oracle Access Manager 10g/11g](#) on page 410

### Settings

PAPM application settings, such as those for users and templates, are configured in one place using **Settings**.

### Policy Migration for CA SSO (SiteMinder)

PingAccess customers migrate the policies created using the legacy WAM provider CA SSO (formerly SiteMinder) with Policy Migration for CA SSO. CA SSO policies are created using three distinct methods that are substantially different from the Ping policy structure. This increases the complexity of migration to Ping.

A typical migration involves:

- New infrastructure deployment
- Integration of PingFederate / PingAccess with the traditional WAM solution
- A complex migration of application policy data that has accumulated over the course of a decade or more.

Policy Migration for CA SSO automates the migration of policies from CA SSO to PingAccess and PingFederate. It creates well-named, standalone, and portable PingFederate and PingAccess policies using data exported from SiteMinder. It can eliminate migration complexities, eliminate time-consuming UI searches, and reduce the errors of manually keyed data.

#### Features:

- **SiteMinder Exports:** Import CA SSO (SiteMinder) XPS export files.
- **JSON-based Format:** Transformation of XPS data into a generic, JSON-based format for easy data manipulation
- **Fast Transformation:** High-speed XML transformation using a background database ETL process.
- **Easy Policy Views:** Single page view of policy data for user convenience. All SiteMinder policy data is compiled on a single page and matched with PingAccess data.
- **Customizable Mapping:** Automatic mapping of policy data into PingAccess objects - with manual manipulation, if required.
- **Auto Build:** Automatic creation of PingFederate OIDC objects including LDAP attribute lookups.

#### Policy Migration for Oracle Access Manager 10g/11g

PingAccess Policy Migration for Oracle Access Manager (OAM) automates the process of exporting OAM authentication and authorization policies to migrate them to PingAccess and PingFederate. PAMP simplifies the migration of OAM policies to PingAccess and PingFederate by exporting the policy domains from both versions to a common JSON format that PAMP can understand. This process helps remove the guesswork of how your application authentication and authorization policies map to the PingAccess and PingFederate format.

Policy Migration for OAM provides three key components to enable the policy migration:

- **An Export and Normalization Module:** This utility can pull policies from OAM 10g or 11g and normalizes the export into a unified format.
- **The Policy Migration UI:** It provides a logical interface to quickly review the components of an application policy before it is imported into the Ping environment.
- **The PAMP OAM Rule Evaluator:** OAM policies often contain highly complex URL matching patterns (a combination of regex and special characters) and policy logic. The PAMP OAM Rule Evaluator loads directly into the PingAccess runtime engine to perform the same URL parsing and policy logic available in OAM. Since this is a plugin authorization engine, it supports policy caching as well.

Together, these components enable secure policy migrations with minimal user interaction and vastly reduce the time involved with the overall migration to the Ping platform.

## Installation and setup

---

Choose from one of the following topics:

- [Installation](#) on page 410
- [Setup](#) on page 413

### Installation

The installation process consists of the following high-level activities:

[System requirements](#) on page 411

[Test connectivity](#) on page 411

[Deploy the PAMP platform](#) on page 411

[Log in to PAMP](#) on page 412

[Import license](#) on page 412

## System requirements

The following prerequisites are required to install the application:

- PingAccess 5.0+
- PingFederate 9.0+
- Oracle Java SE Runtime Environment (Server JRE or JDK) 8 (64-bit)
- System Environment Variable JAVA\_HOME must exist and be set to a value that represents the location of your Java installation (ie; C:\Program Files\Java\jre\_1.8.0\_191).

**Note:** When adding the environment variable entry via the Windows UI, do not place quotation marks around the path.

- Internet Explorer 11 or above, Microsoft Edge, Mozilla Firefox or Google Chrome
- Valid license for PAPM

**Note:** For optimal user experience, PAPM requires a minimum browser window size of 1280px x 1024px.

## Test connectivity

Before setting up the platform, test connectivity to PingAccess, PingFederate, or both, as needed using existing software. The PingAccess and PingFederate servers must be running to configure PAM. Make sure the PingAccess server connects to PingFederate via OIDC connection.

## Deploy the PAM platform

### About this task

This document describes PAM installation for Unix and Windows-based systems. Support for running PAM is provided via shell scripting. There is currently no functionality that allows the product to run as a service.

Prior to starting the installation, the following prerequisites must be satisfied:

- The 64-bit Oracle JRE/JDK must be installed.
- System Environment Variable JAVA\_HOME must exist and be set to a value that represents the location of your Java installation (ie; C:\Program Files\Java\jre\_1.8.0\_191).

**Note:** When adding the environment variable entry via the Windows UI, do not place quotation marks around the path.

- You must have a valid PingAccess Policy Migration license file.
- A PKCS 12 file must be created with the keypair. See [Step 3](#).

## Steps

1. Download the distribution file.
2. Extract the distribution file contents into your Ping Identity installation directory.
3. Add or create a PKCS12 file that contains the PAM keypair.

**Note:** To generate a self signed certificate in Unix that works with the default configuration, run the following command from the PAM home directory:

```
keytool -genkeypair -alias papm -keypass 2Federate -storepass
2Federate -keyalg RSA -keysize 2048 -storetype PKCS12 -keystore
config/keystore.p12 -validity 365 -dname CN=localhost,C=US
```

The file name and location, alias, and credentials can be customized by editing <PAM\_HOME>/config/application.properties.

4. In a command prompt or terminal window, change to the PingAccess Policy Migration bin directory:
  - On Linux: `cd <PAM_HOME>/bin`

- On Windows: `cd <PAPM_HOME>\bin`
5. Initiate the run script for the platform:
    - On Linux: `./run.sh`
    - On Windows: `run.bat`
  6. Secure the PAMP login by configuring the following properties in `<PAPM_HOME>/config/application.properties` as appropriate:

Property	Description
<code>papm.account-locking.login-failure-threshold</code>	The maximum number of consecutive failed login attempts before a user or IP address is locked out. If this property is set to 0, lockout is disabled.
<code>papm.account-locking.lockout-period-minutes</code>	Specifies the duration of the lockout period in minutes. If this property is set to 0, lockout is disabled.
<code>papm.account-locking.ip-address-source.header-names[&lt;value&gt;]</code>	Specifies a header name to search for in the list, where <code>&lt;value&gt;</code> represents the value's location in the list order. Multiple values can be defined (For example, <code>[0]</code> , <code>[1]</code> , <code>[2]</code> ).
<code>papm.account-locking.ip-address-source.list-value-location</code>	Specifies whether, when a list of values is in the header, the first value or the last value in the list should be used as the IP Source value. The default value is <code>Last</code> .
<code>papm.account-locking.ip-address-source.fall-back-to-last-hop-ip</code>	Specify <code>true</code> to indicate that if none of the listed headers is present in the request, the upstream IP address should be used for rule evaluation. If this value is disabled ( <code>false</code> ) and no headers match, the network range rule will return a <code>Forbidden</code> status.

## Log in to PAMP

### About this task

**Note:** For optimal user experience, PAMP requires a minimum browser window size of 1280px x 1024px.

### Steps

1. Open a web browser and type the PAMP URL:

```
https://<servername>:9011
```

**Note:** The port may be customized by editing `<PAPM_HOME>/config/application.properties`.

2. Select and import the PAMP license.
3. Log in using the default credentials: `administrator/2Federate`.

## Import license

### About this task

PAMP requires a valid license to function. If a valid license is not found, you will be asked to import one. To import a license directly into the tool:

## Steps

1. Using the Settings tool, click **License Management** from the left navigation menu.
2. Click the **Select License File** button.
3. Navigate to the license key file location and select the license key file. The path and file name of the license key file display and the license key validation process executes. The license key is stored on the file system: `<PAPM_HOME>/config/papm.lic`
4. Once the key validates, click **Update License** to update the license key.
5. To complete the license key process, log out of the PAPM and then log back in.

**Tip:** To manually update the license:

- a. Rename the updated license file to `papm.lic`.
- b. Use this file to replace the existing license at `<PAPM_HOME>/config`.
- c. Log out of PAPM, then log back in.

## Setup

Once installed, additional setup procedures may be required prior to using PAPM. These are typically one-time setup activities but some may require multiple iterations (such as setting up environments).

- [Change login type on page 417](#) : The default type is initially set to File Login. Typically, PAPM users prefer to use LDAP System Account Login.
- [Change the database password](#) (Optional): Change the database password for increased security.
- [Create Environments](#) : Create an environment in PAPM for each Ping environment.

## Upgrade PingAccess Policy Migration

### Before you begin

This document provides instructions for upgrading a standalone instance of PingAccess Policy Migration.

**To run the upgrade utility, you will need the following:**

- The PingAccess Policy Migration Upgrade Utility archive
- The PingAccess Policy Migration distribution zip file

Copy the required files to the system being upgraded, and unpack the PingAccess Policy Migration Upgrade Utility archive.

Any warnings or errors encountered are recorded in `log/upgrade.log`, as well as on the screen while the utility is being run.

### About this task

Use the PingAccess Policy Migration Upgrade Utility to upgrade PingAccess Policy Migration to a more recent version.

**Important:** Before you upgrade, create a backup of your existing PingAccess Policy Migration configuration. In the event of an upgrade failure, you can restore the backup configuration.

## Steps

1. Stop the running PingAccess Policy Migration instance.
2. Unpack the upgrade utility zip file.
3. Change to the upgrade utility's `bin` directory.
4. Run the PingAccess Policy Migration Upgrade Utility:
  - On Windows: `run.bat <sourcePAPMRootDir> <outputDir> <papmZip>`

- On Linux: `./run.sh <sourcePAPMRootDir> <outputDir> <papmZip>`

For example: `./run.sh pingaccess-policy-migration-1.0 pingaccess-policy-migration-1.0.1 pingaccess-policy-migration-1.0.1.zip`

### Parameter Definitions

The command-line parameters are the same regardless of the platform, and are defined as follows:

Parameter	Value description
<code>&lt;&lt;sourcePAPMRootDir&gt;&gt;</code>	The home directory for the source PingAccess Policy Migration version
<code>&lt;outputDir&gt;</code>	The target directory which will contain the unpacked PingAccess Policy Migration distribution
<code>&lt;&lt;papmZip&gt;&gt;</code>	The PingAccess Policy Migration distribution for the target version

**Note:** In the context of an upgrade, "source" refers to the old version of PingAccess Policy Migration, and "target" refers to the new version.

5. [Start](#) the new PingAccess Policy Migration instance.

## Settings

PAPM application settings, such as those for users, licenses and templates, are configured in one place using **Settings**.

## Environment management

Configure the connection parameters to each of the target PingAccess and PingFederate environments from the **Environment Management** screen. PAPM uses these environment settings to perform all of the policy administration allowed by the tool for each of the paired PingAccess and PingFederate deployments you wish to manage via PAPM.

**Note:** The environments created here are also used for the tracking of audit and policy recovery data. The environment name (for example, dev) is linked to this data. In this version, it is not possible to rename or delete an environment. An environment can be disabled and will disappear in the rest of the UI.

**Important:** If your environment requires the use of TLS Server Name Indication (SNI), use fully qualified domain names when entering the PingAccess and PingFederate host values. SNI is not supported when using hostnames (e.g. localhost) or IP addresses.

**Important:** If your PingAccess or PingFederate admin consoles are behind a reverse proxy and mapped to a path other than /, PingAccess Policy Migration will not be able to connect, as this version of PingAccess Policy Migration uses specific API paths.

Environment parameter	Example value
<b>Hierarchy Index:</b> Numerical index to prioritize the drop down list of environments.	1
<b>Environment:</b> The environment name in all lower case. There must be no leading or trailing spaces.	dev

<b>PA API Version:</b> Version number of the PingAccess API REST URL. It is also linked to the set of Java data beans that carry the compatible versioning structure to allow for backwards and forwards version pushes.	v3
PingAccess 3 = v1 API	
PingAccess 4 = v2 API	
PingAccess 5 = v3 API	
<b>PA Agent Listener [&lt;Host&gt;:&lt;Port&gt;]:</b> This is the agent listener hostname and port that is used to create PingAccess Agents and their associated <code>bootstrap.properties</code> .	mysaserver:3030
<b>PA Engine Listener [&lt;Host&gt;:&lt;Port&gt;]:</b> The engine listener hostname and port to connect to the PingAccess Proxy. This is used by the PingAccess Test Tool to create PingAccess engines and their associated <code>bootstrap.properties</code> .	mysaserver:3000
<b>PA Admin Host [&lt;Host&gt;]:</b> Hostname of the PingAccess administrative host node (or VIP) used to connect to the PingAccess Administrative API to allow PAM to read and update configuration used for policy administration and migration use cases..	mysaserver
<b>PA Admin Port [&lt;Port&gt;]:</b> PingAccess administrative host port.	9000
<b>PA LoginType:</b> Basic authentication (username / password) or API authentication to the PingAccess admin APIs.	Basic
<b>PA Username:</b> Administrative username for PingAccess.	Administrator
<b>PA Password:</b> PingAccess admin password.	mysapassword
<b>Note:</b> To change the password when updating an existing environment, clear the password and enter a new value. Otherwise, leave the password unchanged.	This field is rendered as masked values (*).
<b>API Scope:</b> PingAccess API login scope (only used for API-based authentication).	Admin
<b>API Granttype:</b> PingAccess API Grant Type used for API authentication.	client_credentials
<b>API ClientID:</b> PingAccess OIDC API Client ID configured in PingAccess and PingFederate.	admin_api_client
<b>API Client Secret:</b> PingAccess API Client Secret that was configured for the OIDC client.	myapipassword This field is rendered as masked values (*).
<b>API TokenURL[&lt;Host&gt;:&lt;Port&gt;/&lt;URL&gt;]:</b> The PingFederate API Token Login URL.	https://pfsaserver:9031/as/token.oauth2
<b>PF Admin Host [&lt;Host&gt;]:</b> PingFederate administrative host node (or VIP).	mypfsaserver

<b>PF Admin Port</b> [<Port>]: PingFederate administrative host port.	9999
<b>PF Username:</b> An administrator login name with access to the PingFederate API's.	Administrator
<b>PF Password:</b> The PingFederate administrative password for the user configured above.	myfpfpassword This field is rendered as masked values (*).
<b>Note:</b> To change the password when updating an existing environment, clear the password and enter a new value. Otherwise, leave the password unchanged.	

## Create a new environment

### About this task

This section contains information about setting up environments in PingFederate and PingAccess. PAPM requires at least one environment.

### Steps

1. Using the Settings tool, click **Environment Settings** on the left navigation menu. The environments previously created will display as buttons on the screen.
2. Click **Create New**.
3. Input the information for the new environment and click **Save**.  
The environment builds. Once complete, a success message displays.

The system will display a message if it is unable to connect to an environment. If you are unable to connect to an environment, check the following:

- Ensure the hostname is correct and that it is reachable.
- Ensure the hostname matches that of the TLS certificate. The certificate hostname should match the hostname for the system on which the product is installed.
- Ensure the ports are correct and accessible.
- Ensure usernames and passwords are correct.

## License management

Use the **License Management** screen to add or update a new PAPM license file.

See [Import license](#) on page 412 for more information.

## Application settings

The **Application Settings** menu configures PAPM authentication. To access this screen, navigate to **Settings > Application Settings**.

- Select from the **Policy Suite Sign-on** list to specify the active login module.
- To change modules, select the module and click **Save Configuration**.

**Note:** PAPM supports user accounts and password storage in either an embedded database or via LDAP.

### Database Login

Database Login is the default login type when PAPM installs for the first time. We recommend using LDAP as the user store for enhanced security and availability.

- Administrators give access to users by assigning username and password combinations for each user in the user interface.

## LDAP Login

LDAP Login module provides simple authentication with group-based authorization. Configure the following values to enable LDAP Login. More information on these values can be found in Spring Security documentation found [here](#) and [here](#).

**Note:** In the event that LDAP Login is misconfigured, resulting in a lockout, you can force Database Login by setting `papm.force-database-authentication` to `true` in `application.properties`.

Field	Description
LDAP URL	URL of the LDAP Server. For example: <code>ldap://example.com:389/dc=example,dc=com</code> .
USER DN PATTERN	The login user's DN pattern. For example: <code>uid={0},ou=people,{0}</code> must be present and will be substituted with the username. Optional if User Search Filter is configured.
USER SEARCH FILTER	The login users search filter. For example: <code>(uid={0})</code> . <code>{0}</code> will be substituted with the username. Optional if User DN Pattern is configured.
USER SEARCH BASE	The search base for user searches. Only used with a User Search Filter. If omitted, defaults to root search.
GROUP SEARCH FILTER	The group search filter. For example: <code>(uniqueMember={0})</code> . <code>{0}</code> will be substituted with the DN of the user. <code>{1}</code> can be used if you want to filter on the login name.
GROUP SEARCH BASE	The search base for group membership searches. If omitted, defaults to root search.
GROUP ATTRIBUTE	The LDAP attribute name which contains the group name. For example: <code>cn</code>
ALLOWED GROUPS	The groups allowed for access to PAPM. Separate multiple groups with ' '. Allow any group with '*'.
MANAGER DN	The DN of the LDAP account used by PAPM to connect to the LDAP server. Optional if anonymous access is used.
MANAGER PASSWORD	The password for the LDAP account. Required only if Manager DN is specified.

## Change login type

### About this task

When PAPM is first installed, the login type is set to Database Login. However, **LDAP Login** is the most common login type for PAPM. This section describes the process to change the login type to LDAP Login.

### Steps

1. Using Settings, click the **Application Settings** link from the left navigation menu. The **Application Settings** screen displays.
2. Select the desired login type in **Policy Suite Sign-on** list box.

The information needed for the selected login type displays. See above for detailed login type information.

3. Type login type information and click **Save Configuration**.

**Note:** You must input valid LDAP information to prevent a lockout when changing login type. It is possible to leave a browser logged in and open a second browser to test the login type change.

**Note:** In the event that LDAP Login is misconfigured, resulting in a lockout, you can force Database Login by setting `papm.force-database-authentication` to `true` in `application.properties`, and restarting PAPM.

4. If Secure LDAP is used, add the trusted certificate used by the ldap service to the JRE truststore:

**For example:**

```
keytool -import -trustcacerts -file /path/to/ca/ca.pem -alias CA_ALIAS -
keystore $JAVA_HOME/jre/lib/security/cacerts
```

## Database management

**Database Management** contains the following functionality:

- **Current Statistics:** View the database estimated row count
- **Archive Settings:** Manage the size of PAPM databases.

Settings, audit records, and application data are stored in the database. The database auto-archives itself every day and maintains 10 backup copies in the `<PAPM_HOME>/config/DB/BACKUP` directory. Manual user intervention is not required for this backup to occur.

### Archive Settings

To manage the growth of the database, use Archive Settings. For each of the tools that use the database, input a maximum number of records (rows). PAPM checks the row count nightly to determine if the row count exceeds the limit set by the user. If it does, PAPM creates a CSV archive file containing the oldest inserted records in the database. The number of records in the archive file is the number of records that are over the limit.

For example, two records are added to a database containing six records. If the user has set the record limit to six, the additional two records exceed the record limit. PAPM archives this data at the end of the day by creating a CSV file containing the data for the first two records (the oldest records) in the database. Next, PAPM removes these records from the database and brings the record count back down to the limit set by the user.

The size of an audit record can be between 500 bytes and 20,000 bytes. An archival setting of 10,000 records with an average size of 10,000 bytes per record will result in 100MB of data.

### Manage the size of the database

#### About this task

To manage the size of the database that stores PAPM data, set the maximum number of records for each database.

#### Steps

1. Using the Settings, click the **Database Management** link from the left navigation menu.
2. Click **Archival Settings**.
3. For each of the tools, type a value that the tool must reach before it starts archiving the data for that tool.

## Customize the number of database backups

### About this task

To customize the number of database backups:

### Steps

1. Open `<PAPM_HOME>/config/application.properties`
2. Using the `papm.database.max-backups` property, specify the maximum number of backups.

## Revert to a previous backup

### About this task

To revert to a previous backup:

### Steps

1. Shut down PAPM.
2. Remove or backup the associated database files (all end in \*.db, \*.lock, \*.part), in the following directory: `<PAPM_HOME>/data`
3. Copy the backup ZIP file from the `<PAPM_HOME>/data/backup` directory into `<PAPM_HOME>/data`.
4. Unzip the file into `<PAPM_HOME>/data`
5. Restart PAPM.

## Change configuration database passwords

### About this task

The PingAccess Policy Migration configuration database is protected by two passwords - a file password and a user password. These passwords both default to `2Federate`, but should be changed for production environments. To keep your data secure, change the password to the PAPM database.

**Note:** Changing either password requires PingAccess Policy Migration to be shut down.

**Tip:** It is recommended to use a key pair with a different password from the system default, and further recommended to obfuscate this password using the `obfuscate.bat/obfuscate.sh` utility in `<PAPM_HOME>/bin`. Add the obfuscated password to `<PAPM_HOME>/config/application.properties`.

### Steps

1. Open a terminal window and change to the `<PAPM_HOME>/bin` directory.
2. Ensure that the `JAVA_HOME` environment variable is set correctly by executing the command `echo $JAVA_HOME`.
3. Ensure that the proper Oracle Java executable is in your path. Enter the command `java -version`. If this command returns a value indicating that the Java executable is not a supported version of Oracle Java, correct this issue before continuing.
4. Shut down PingAccess Policy Migration.
5. Optional: To change the database file password, use the following commands:
  - On Windows: `dbfilepasswd.bat old_password new_password`
  - On Linux: `./dbfilepasswd.sh old_password new_password`
6. Optional: If you changed the database file password, update the `papm.database.file-password` property in `<PAPM_HOME>/config/application.properties` with the obfuscated password output from the command used in the preceding step.
7. Optional: To change the database user password, use the following commands:

- On Windows: `dbuserpasswd.bat file_password old_password new_password`
  - On Linux: `./dbuserpasswd.sh file_password old_password new_password`
8. Optional: If you changed the database user password, update the `papm.database.password` property in `<PAPM_HOME>/config/application.properties` with the obfuscated password output from the command used in the preceding step.

## SSL certificates

### Steps

1. Create a self-signed certificate using the Java Keytool. The following command generates a key pair and certificate directly into file keystore. For example:

```
keytool -keystore config/keystore.p12 -alias papm -genkey -keyalg RSA
```

**Note:** If a file named keystore already exists, make a backup. This command prompts you for information about the certificate and for passwords to protect both the keystore and the keys within it. The only mandatory response is to provide the fully qualified host name of the server at the "first and last name" prompt.

2. Generate a CSR (Certificate Signing Request). For example:

```
keytool -certreq -alias papm -keystore config/keystore.p12 -file papm.csr
```

**Note:** The default location of the keystore is `<PAPM_HOME>/config`.

3. Send the CSR to a certificate authority to be signed.
4. Obtain the signed certificate.
5. After receiving the signed certificate, load it into the truststore using the following command:

```
keytool -keystore config/keystore.p12 -import -alias papm -file papm.crt -trustcacerts
```

6. To obfuscate the password, navigate to the `<PAPM_HOME>/bin` directory, type the applicable filename and press **Enter**. You will be prompted to enter the password you want to obfuscate.

- **Windows:** `obfuscate.bat`
- **Linux:** `obfuscate.sh`

7. Open `PAPM_HOME/config/application.properties` and configure or update the SSL properties.

- `server.ssl.key-store=${papm.home}/config/keystore.p12`
- `server.ssl.key-store-type=PKCS12`
- `server.ssl.key-store-password=2Federate`
- `server.ssl.key-password=2Federate`
- `server.ssl.key-alias=papm`

8. Start the server by executing the following command:

```
./run.sh
```

## Version

This section displays PAPM version information.

## Monitoring Dashboard

The PAPM Monitoring Dashboard provides real-time environment status for Ping Identity services. It also provides a historical view of activity to aid in troubleshooting. The monitoring console is designed to be flexible enough to work with third-party web applications.

### Summary health check

Summary health check displays the status of active monitors by their environment and status. It provides a single health status view of the various Ping servers. This view can quickly alert an administrator to current or escalating issues.

#### Health check status indicators

A status color of Green, Yellow, or Red is assigned to each service URL identified by PAPM in the Active Monitor list.

<b>Healthy (Green)</b>	The Green status indicator denotes a healthy active monitor. Monitoring Dashboard has not identified any issues with connectivity, use, etc.
<b>Sync Failure (Yellow)</b>	The Yellow status indicator denotes a sync failure. In the event of a sync failure, the monitor will set the entire environment to this status. Check the Sync Status UI for details on the failed component(s). If an environment has both a sync failure AND a status failure, then the status of the environment will change from yellow to red.
<b>Active Failure (Red)</b>	In the event of an active failure, the monitor will set the environment to red and move the offending service check to the top of the Active Monitor queue. The dashboard only shows heartbeat data for an environment by default. If an offending monitor does not show up on the list of active monitors, remove the heartbeat search filter and refresh.

#### Sort Order

The Active Monitor list displays an inventory of all known services. Issues across the system or within a given environment display at the top of the list. This list sorts in the following order:

- 1. Status:** If any individual monitor has an error response, it sorts first.
- 2. Environment:** All monitors sort by their environment definition next.
- 3. Response time:** Finally, the list sorts by the response time. Hence, the first successful entry for any environment will be the slowest responding service.

To configure a summary health check, see [Add a new monitor](#) on page 424.

**Tip:** Define flexible environments for improved readability. For example, instead of defining an environment like 'prod', define multiple environments like 'prod-dc1' and 'prod-dc2' to isolate issues within a specific data center and enhance native sorting based on response times.

### Response times

**Response Times** provides a graphical display of historical and live response times as well as CPU Load and Open Connections comparisons for Ping servers. Monitor URLs that connect to a PingAccess proxy port heartbeat to see the activity of open proxy connections.

To view response time data, you must have active monitors in an environment.

1. Select the **Environment** for which you want to view response time data.
2. Select the monitor **Name(s)**.
3. Specify whether monitoring is **Enabled** or **Disabled**.
4. Specify the **URLs** you want to monitor.
5. Click **Draw Charts**.
6. Review historical data by specifying a date range in the dropdown.

To configure a response time display, see [Add a new monitor](#) on page 424

## Memory usage

Memory usage charts show the total, free, and used system memory available to the JVM. A healthy JVM should show regular garbage collections and variable memory usage related to system utilization, but not a net increase of memory usage over time.

The system monitor provides an overview of the available memory and its utilization. If JVM memory does not show a healthy garbage collection process or free memory, ensure the JVM argument sizing is appropriate in the Ping start scripts.

To view memory usage data, you must have active monitors in an environment.

1. Select the **Environment** for which you want to view response time data.
2. Select the monitor **Name(s)**.
3. Specify whether monitoring is **Enabled** or **Disabled**.
4. Specify the **URLs** you want to monitor.
5. Click **Draw Charts**.
6. Review historical data by specifying a date range in the dropdown.

To create a memory usage monitor, see [Add a new monitor](#) on page 424

## Sync status

Sync status offers a Ping-specific monitoring feature that ensures servers within an environment (cluster) are synchronizing PingFederate and PingAccess JSON web keys and PingAccess application policies appropriately. It automatically places heartbeat endpoints based on the configured monitor URL and the assigned environment. The first server in the sync group determines the reference version of data.

- **Run Comparison:** Click to refresh the screen to get a real-time current view of the status.
- **PingAccess Database Sync:** Validates the heartbeat endpoints for an environment to ensure that they contain the same number of configured applications, virtual hosts, and proxy sites.
- **PingAccess JWKS Sync:** Tests all JWKS endpoints within an environment to ensure that all services are using the same set of keys.
- **PingFederate JWKS Sync:** Tests all JWKS endpoints within an environment to ensure that all services are using the same set of keys.

To create a sync status monitor, see [Add a new monitor](#) on page 424

**Note:** If servers that do not belong in the same cluster are paired under the same monitoring environment, this console will always show failures.

**Note:** If a reference server is the endpoint that is out of sync, the UI will mistakenly show all of the other servers as out of sync. It is not possible to query the admin node via a web interface for the correct reference data.

## Search

Search provides an interface to search historical events and responses. You can search and sort archived data using predefined parameters.

- Select a **Monitor** and click the arrow to render available dates.
- Specify a date to search.
- Click **Display Data**.
- In the search results list, sort by event times, response times, and status
- Click the **Event Time** hyperlink to inspect the text response from any monitor.

## Manage monitors

Add a new monitor from **Manage Monitors**. Three MB of disc space of data per monitor per day on a 60-second interval is required.

Custom monitoring URLs have different storage requirements related to the page size. The monitor console has a download limit of 10 KB per page. If the test URL needs to download more than 10 KB of data, then it will fail. This limitation prevents storage exhaustion.

- **Environment:** Each monitor URL should be tied to the correct environment (e.g. Dev, Test, QA, Prod). The environment is more than a descriptor; it is also used to sort errors and eventually feed the health status of the entire environment.
- **Monitor Name:** The Monitor Name should include a descriptive title that is searchable. For example: "Svc Name *ServerName*" "PA JWKS *Server15*"
- **Monitoring URL:** The Monitoring URL is the endpoint that the monitor will call to test the target service.
- URLs that contain the strings: "/pf/JWKS, /pa/JWKS, /pa/heartbeat.ping" are treated differently from other URLs and are evaluated in the key and engine sync tests.
- **Monitoring Interval:** Monitoring Interval is used to configure the wait time between tests. This value directly affects the data storage requirements. For example, a 30 second interval will require 2x as much storage as a 60 second interval.
- **Success Criteria:** A monitor reports success or failure based on this attribute.
  - **Default:** HTTP/200 Response Code (will succeed with any response code in the 200 range)
  - **Contains:** Must contain the case-sensitive, substring in the HTTP Response Body (not in the response headers).
  - **Regex:** Java Regex match within the HTTP Response Body. Use the test Monitor function to refine the regex. Example: `.*("number.of.virtual.hosts": "[0-9][0-9]")`.
- **Enabled:** A monitor should generally always be enabled. Use this option to disable a monitor during known system downtimes to suppress errors and alerts.
- **Username / Password:** Add a username and password if the resource requires the basic authentication header to be added to the request. Passwords are encrypted in the database.
- **Additional Header:** Some service calls may require additional headers. For example, an API test against the PingAccess APIs requires a X-Xsrf header.
- **Proxy & Archival Settings** button: See [Proxy and archive settings](#) on page 424.

## PingAccess enhanced heartbeat messages setup

### About this task

#### Steps

1. In PingAccess, open `<PA_ROOT>/conf/run.properties` and set `detailed.heartbeat.response` to **true**.
2. Configure `<PA_ROOT>/conf/template/heartbeat.page.json` to have the appropriate attributes.
3. Save the files and restart PingAccess.

**Tip:** Although hostname is not required, it is best practice to add a unique, opaque identifier in the hostname field for agent/proxy identification.

## PingFederate enhanced heartbeat messages setup

### About this task

#### Steps

1. On the PingFederate server, open `<PF_ROOT>/bin/run.properties` and set `heartbeat.system.monitoring` to **true**.
2. Ensure the heartbeat template includes at minimum the parameters to measure memory and load statistics. Open the `<PF_ROOT>/server/default/conf/template/heartbeat.page.template` and check that the memory and load parameters are available in the template.
3. Additional parameters can be configured, but may not be used directly by the Monitoring Dashboard.
4. Save the files and restart PingFederate.

**Tip:** If your site has already configured load balancers to use the “OK” response message from the default heartbeat template, then simply add the “OK” text into the template.

### Add a new monitor

#### About this task

1. Using Monitoring Dashboard, click the **Manage Monitors** link from the left navigation menu.
2. Input information for the new monitor in the **Create New Monitor** screen. See [Manage monitors](#) on page 423 for more information.
3. Click **Test Monitor** to ensure the monitor works as expected.
4. Click the **Create New Monitor**

### Delete a monitor

#### About this task

#### Steps

1. Using Monitoring Dashboard, click the **Manage Monitors** link from the left navigation menu.
2. In the **Existing Monitors** list, click the delete icon for the monitor to remove.

### Proxy and archive settings

The monitoring service can be configured to use a forward proxy to test URLs.

- If a proxy is set, monitors will attempt to use the proxy interface.
- Configures the number of days to retain historical data.
- This is a global setting and affects all monitors.

To access these settings, navigate to **Monitoring Dashboard > Manage Monitors** and click the **Proxy & Archive Settings** button.

## Policy Automation

---

Policy automation allows the administrator to migrate configuration elements for PingAccess, to migrate all of the configuration elements for a PingAccess application based on templates, set conditions on what to do in target environments when changing PingFederate/PingAccess configuration, and to promote policy between operational environments. It can also export policies and store them in an auditable flat file database or show the difference between two policies.

## Policy promotion process overview

Policy migration is a web based deployment and management solution that works with PingFederate and PingAccess. This diagram shows the typical process flow for policy promotion from DEV to TEST environments.

An application policy and all of its dependent policy objects are exported from the development environment into the PAMP database. The PAMP module transforms the source environment data to match the target TEST environment and calls the APIs to import the new application policy objects. The application and all of its required components are now available in the target environment.

**Tip:** PingAccess Policy Migration supports dynamic policies to handle conflict conditions. For example, during the import process, if there is already an existing object, PAMP can be configured to link to the object instead of overwriting it. In the case of a failure condition, PAMP can either roll an object back or leave the updated data in place.

**Note:** PAMP uses the management APIs of PingFederate and PingAccess. Make sure the required administrative consoles are running and accessible from the PAMP.

To ensure accuracy, validate the following settings after a policy is promoted using PAMP:

- Virtual host Certificates
- Site Certificates
- Site Load Balancing
- Websession Cookie Domain

## Policy Operation

Promote, export, and remove applications from the **Policy Automation > Policy Operation** screen.

The first section of the **Policy Operation** screen defines the source application:

1. **Environment:** Displays list of available environments. Select the environment containing the applications that need to be loaded.
2. **Connection Type:** Select the application type. Available applications for the selected environment and connection type populate the **Connection** list box.
3. **Connection:** Select the application policy from the list of available applications from this environment
  - **View Application Details:** Click this icon to display application artifacts in a pop-up window.

The next two sections of the **Policy Operation** screen define objects selected for the application in the first section.

1. **List Releases** button: A release occurs when an export promotes to an environment. Click to load the list of packages released for the selected application.
2. **List Exports** button: A exports is a version the application at a point in time. Click to display all prior exports of this application.

**Note:** You must create at least one export in order to populate this list.

3. **Select Package:** Select the package to release into target environment.
  - View Package Details icon: Click to display details of export/package in a pop-up window.
4. **Target Environment:**
  - **Change Number:** Type the release label for the target environment.
  - **Select a target environment**
  - **Publish:** Click this button to push the selected export to target environment.
5. **Upload Package** button: Click to select a package to upload.

Action buttons are found at the bottom of the screen.

1. **Export Application:** Click this button to export current application from this environment and creates an export with unique identifier as per below format: [YYYY-MM-DD HH:MM:SS.zzz>sequencing number]. g.:2017-02-01 21:30:56.233 > 238
2. **Remove Application:** Click this button to remove the selected application from source environment. It removes all dependent components as well.

### Publish Package

The **Publish Package** screen displays when clicking the **Publish** button from the **Policy Operation** screen to allow users to configure the publish operation. For example, users can change the target application name if needed.

### Load an application

#### Steps

1. Using Policy Automation, click the **Policy Operation** link from the left navigation menu.
2. From the **Environment** drop-down list box, select an environment.
3. Click the **Environment load** button to load the selected environment.  
The applications for the selected environment populate the applications drop-down list box.
4. From **Connection Type** drop-down list box, select connection type.
5. From the **Connections** drop-down list box, select an application.

### Promote a policy

#### About this task

The Policy Promotion component automates policy promotion from one environment to another. This component automatically assigns environment specific virtual host names and a target proxy site. Use this procedure to promote a new policy or publish a previous version of a policy.

#### Steps

1. Click the **Policy Operation** link from the left navigation menu and follow the steps to load the application.
2. Click the **List Exports** button to load the available exports for this application.

The available exports populate the page. If there are no previous exports at this point, create the export first.

3. Select the export from the list of available exports of the **Package Selection**.  
The export details populate the page.
4. (Optional) Type a release number in the **Target Environment Change Number** text box. Releases should be unique and easily identifiable.
5. Select the **Target**. If promoting a policy to a new environment, the target environment will differ from the source environment selected when loading the application in the first step.
6. Click the **Publish** button below the Target Environment list box.  
The **Publish Package** screen displays.
7. On the **Publish Package** screen, choose **Active** or **Inactive**. If needed, modify the **Application Name** and **Context**.
8. Select an **Operational Policy** from the **Policy** list box. Operational Policies are user created in PAPM and define how PAPM handles object during processing.
9. Type a **Virtual Host** and **Site Target(s)**.
10. Click the **Publish** button.
11. Validate the application published to the target environment.
  - **Target Application Name:** Populates with the source application name and should not typically be changed. Users can customize the target application name to include the name of the target environment. For example, change the name from AppDev1 to AppDev2. This can be useful to support multiple application environments with a single Ping environment.
  - **Policy:** Operational policies specify how PAPM will behave during create and push operations. See [Building operational policy](#) on page 431 for more information.

If the policy fails to publish, details of the failure are documented in **Audit Data > Other Audit**. Pick the link associated with the application name that you were attempting to publish. Details of the configuration are documented on the PingAccess or PingFederate Release Data pages.

### View application details

#### Steps

1. Using Policy Automation, click the **Policy Operation** link from the left navigation menu and follow the steps to load the application.
2. Click the **View Details** button located on the right side of the **Connections** dropdown list.

### Create an export

#### Steps

1. Using Policy Automation, click the **Policy Operation** link from the left navigation menu and follow the steps to load the application.
2. Click the **Export Application** button to export the application from source environment.  
For IDP and SP connections, the policy is exported.  
If the selected application is a PingAccess API, The **Select OIDC Client for API application** screen displays.
3. For PingAccess applications, select an OIDC client from the list then click **Export Application** to export the policy.

### View the export list

#### Steps

1. Using Policy Automation, click the **Policy Operation** link from the left navigation menu and follow the steps to load the application.

- To load the export list, click **List Exports**.  
Previous exports populate the **Exports > ConnectionType > Env** list.

**Note:** A warning is displayed if no exports exist. To create an export, see [Create an export](#) on page 427.

- Click the **Exports > ConnectionType > Env** Down Arrow to view the list.

### Download a package

#### Steps

- Using Policy Automation, click the **Policy Operation** link from the left navigation menu and follow the steps to load the application.
- To load the export (package) list, click **List Exports**.  
Previous exports populate the **Exports > ConnectionType > Env** list.  
**Note:** A warning is displayed if no exports exist. To create an export, see [Create an export](#) on page 427.
- Select an export from the **Exports ConnectionType Env** list.
- Click the **Download** icon for the selected export.  
The export downloads to the downloads folder.

### Upload a package

#### Steps

- Using Policy Automation, click the **Policy Operation** link from the left navigation menu.
- Click **Upload Package**.  
The **Publish Package** screen displays.
- Click **Publish**.

## Policy Settings

Policy migration requires a connection to PingFederate and PingAccess environments to access API data. These connections allow PAPM to export policy data, manage policies, and push policies to target environments such as DEV or TEST. See [Settings](#) on page 414 for more information.

The procedures in this section are used to configure components that are required for policy creation.

### vHost management

To enable 1-Click operations, PAPM tracks changing environment data in its own database. vHost management updates virtual host data and synchronize that data to both PingAccess (virtual host entries) and PingFederate (whitelisted URLs in the OIDC client).

To access this screen, navigate to **Policy Automation > System Settings > Virtual Host Management (PingAccess)**.

- **Environment:** Contains available environments.
- **Select Application:** Contains available applications for the selected environment
- **Edit Virtual Host:** Enter the modifications for host name or port number as host:port
- **Virtual Host: Policy Tool:** This displays existing virtual hosts configured for the selected application.
- **Update VHost:** Updates any necessary changes to existing virtual host configurations in PingFederate and PingAccess.
- **Remove VHost:** Enter the virtual host and port pair then click the **Remove vHost** button to delete the vHost. You cannot delete a virtual host that is assigned to an application.

## Manage vHosts

### Steps

1. Using the Policy Automation, click the **System Settings** link then select **vHost Management** from the left navigation menu.  
The **Virtual Host Management (PingAccess)** screen displays.
2. Select an environment from the **Environment** drop-down list box.  
The applications for the selected environment populate the **Select Applications** drop-down list box.
3. From the **Select Applications** drop-down list box, select an application.  
Name and port number display for the selected application.
4. To add a virtual host, click the **Add** link, specify the `virtual host:port` combination, and click **Update**.
5. To update the host name or the port number, enter the necessary changes to host name or port number in the editable text box, and click the **Update VHost**.  
The host name, port number, or both are updated.
6. To delete a virtual host, click the **Delete** icon to the right of the virtual host entry in the list.

**Note:** Each application requires at least one virtual host setup. Default virtual host configuration cannot be deleted.

### Site management

The **Site Management** screen updates proxy targets and synchronizes that data to both PingAccess and PingFederate.

- **Environment:** This drop down list display list of all environments that were configured previously on setup.
- **Select Application:** This drop down list of available applications from the selected environment.
- **Edit Site:** Enter the modifications for host name and port number pair as **host:port**
- **Add Site:** Click the **Add** link and enter the `host:port` combination for the site.
- **Update Targets:** Click the Update Targets button to update to target environment.
- **Update Site Configurations:** Click this button to display complete site configuration for this application in a new screen and that allows modifications to site configuration.

### Site Update

The Site Update screen provides a way for users to input a new site. You can also update a site or delete a site that is not in use by an application. To access this screen, click **Update Configurations**.

- **Targets:** Multiple targets separated by a comma.

### Certificate management

PingFederate makes extensive use of digital certificates. Configure PAPM with default signing and decryption certificates used for 1-Click creation of SAML connections. The **Certificate Management** screens provide an interface to manage these system defaults.

- **Signing and Decryption Keys and Certificates:** Contains the list of certificates available for signing and decryption. In PingFederate, these establish and maintain the server's signing certificates, which may be used to sign assertions, security tokens, requests, and responses. These certificates may also be used for decryption.
- **SSL Client Keys & Certificates:** Contains a list of client keys and certificates used for TLS authentication to systems that may require it.
- **Import Certificate (PKCS12):** Import a certificate.

## Add a new certificate

### Steps

1. Using Policy Automation, click the **System Settings** link to open this section in the left navigation menu then click **Certificate Management**.
2. Select an **Environment**.
3. Click **Import Certificate**.
4. Select a certificate type then click the **Select Certificate File** button to select a certificate file.
5. If needed, enter a password.
6. Click the **Save Certificate**.

### Datastore management

The **Datastore Management** screen maps unique LDAP and database IDs from the various environments. As PingFederate SAML connections or OAuth configurations are pushed from one environment (DEV) to another (TEST), the system needs to dynamically map these unique IDs. This function is critical to the 1-Click Promotion capability.

**Note:** Datastore mappings should be setup with the initial system deployment and updated whenever new datastores are added.

- **Map Datastore:** Select a source and target environment to map. The UI reads the available data store IDs and makes them available for simplified mapping.

**Note:** Forward and reverse mappings are required. For example, in a deployment with two environments (DEV, PROD), you must map the data stores from DEV to PROD. If you ever plan to push a policy from PROD back to DEV, then you must map the data stores in the opposite direction as well (PROD to DEV).

### Map environments

#### About this task

The following process describes how data stores map between environments.

#### Steps

1. Using Policy Automation, click **System Settings**, then click the **Datastore Management** link from the left navigation menu.
2. Select an Environment (Source) and Environment (Target) and click **Map Datastore**
3. For both environments, select a JDBC and LDAP.
4. Click **Save Configuration**.

### Template management

Templates are the basis of all single click application creations. The vast majority of application policies share a number of attributes. Using well-formed templates that match the security rules and internal security policies can revolutionize the operational workflow for policy administrators.

To access this screen, navigate to **Policy Automation > System Settings > Template Management**.

#### Create Template Application

The Create Template Application function will automatically generate a PingAccess application policy and all of its dependent components in a well-named, portable format. You can modify this policy to meet requirements. This quick start method prevents administrators from making small errors in naming. Once the application is created, you can manage it from PingAccess.

#### Add Application as Template

This function marks an existing application policy as a template and makes it available as a template in the **Migration UI**.

- Click the **Add Application** icon to associate the selected application with the template.

### Delete Application as Template

This function removes an existing template. The application that the template is based on is not deleted.

- Click the **Delete icon** to delete the selected template (does not delete the application policy).

### Create a template

#### About this task

PAPM allows developers to define templates for applications. This can be very useful to onboard similar applications. Existing applications can be marked as a template and applications are created using the existing applications settings.

PAPM templates are based on a three-step principle:

- **Step 1: Create Template:** Create the template from existing application.
- **Step 2: Create Application from Template:** Create the new applications from template. This eliminates the manual steps involved in creating OIDC configuration, web session configuration, and identity mappings configurations for applications of similar setups.
- **Step 3: Modify New Application:** Update and fine-tune the application created.

#### Steps

1. To create a template: Using Policy Automation, click the **System Settings** link then select **Template Management** from the left navigation menu.
2. From the **Environment** drop-down list box, select an environment. Click the **Environment load** button to load the available applications.
3. Click **Create Template Application** to expand the template create section.
4. For PingAccess applications, select the type of template. **Agent** or **Site**. The **Create Template Application** function is only available for PingAccess as it helps to generate a number of complex policy objects.
5. Type the name of the template application in the text box.
6. Click the **Create** button to create the template application. At this point **Template Application** does not have functioning application data associated. You may need to update the host name or virtual host. The following message displays: **Creating Template Application successful**.
7. Click **Add Application AS Template** to expand **Add Template**. Select the Application.
8. Click the button to associate specified application data with the template application.
9. Use the PingAccess and PingFederate Administration Consoles to modify the template configurations as needed.

### Building operational policy

As policy data is pushed around between environments, Policy Automation must deal with conflicts. For example, if a policy is promoted and one of the API calls fails, should PAPM roll the policy back to the original data or leave the partial data in place? If existing objects are found, are they overwritten or reused? Operational Policies manage these situations.

To access this screen, navigate to **Policy Automation > System Settings > Build Operational Policy**.

- **Policy Type:** Choose the policy type as **PingFederate**, **PingAccess**, or **OIDC**.
- **Operation:** Select **Create-Operation** or **Push-Operation** for the policy operation
- **Policy Name:** Contains the name of the operational policy.
- The list in the **Create/Edit Policies** section and the list of saved actions in the **Existing Policies** section change based on the policy type and operation selected.

- To create a new operational policy, enter a policy name, and choose settings in the Create/Edit Policies section and click the **Save Policy** button.
- **Create-Operation Actions:**
  - **Delete on failure:** Applies to Rollback. If the policy build fails when PAMP is creating a Ping policy set, select this action to delete the object set.
  - **Keep Objects:** Applies to Rollback. If the policy build fails when PAMP is creating a Ping policy set, select this action to keep the objects instead of deleting them.
  - **Re-Use if present:** Applies to all actions except for Rollback. When PAMP is creating a Ping policy set, PAMP will re-use the objects found in the template.
  - **Create New:** Applies to all actions except for Rollback. When PAMP is creating a Ping policy set, if an object with the same name already exists, create a new object instead re-using the existing object. This new object is assigned a unique name based on the input application name.
- **Push-Operation Actions:**
  - **Revert to Original:** Applies to Rollback. If an error occurs that prevents PAMP from completing the push of a policy to a new environment, remove any objects that created / updated and keep existing objects.
  - **No Change:** Applies to Rollback. If an error occurs that prevents PAMP from completing the push of a policy to a new environment, save the partially updated objects in place.
  - **Link if Present:** Applies to all actions except for Rollback. When pushing a policy to a new environment, link to existing objects instead of updating or overwriting objects.
  - **Update if Present:** Applies to all actions except for Rollback. When pushing an operation to a new environment, replace existing objects with the new objects included in the push.

### Building an operational policy

Most create-operation type operational policies should create new objects and most push-operation type policies should update objects in place rather than linking to existing objects. While this will result in more objects and a larger policy store, the store will be more portable, stable, and predictable. Imagine pushing a policy that results in no behavior change or that results in multiple policies changing because they share a dependency.

1. Using Policy Automation, click the **System Settings** link then select **Build Operational Policy** from the left navigation menu.

The **Build Operational Policy** screen displays.

2. Select a policy type.
3. Select the policy action.

The fields in the **Create/Edit Policies** section change based on these selections.

4. Enter a name for the operational policy in the **Policy Name** text box.
5. Select an action for the remainder of the fields in the **Create/Edit Policies**
6. Click the **Save Policy** button.

## Compare Exports

### About this task

**Compare Exports** finds differences in application policy versions or SAML connections. For example, it will show the differences between an application in the development and production environments.

- **Environment:** This drop down list displays list of all environments previously configured.
- **Application Name:** This drop down list displays all applications for selected environment.
- **Export:** This drop down list displays available exports of selected application.
- **Compare:** Click this button to compare the selected exports for differences.
- **Results:** This section is the third column on the screen and it displays the differences (highlighted).

**Note: Cipher Data:** As policies are pushed and shared, secrets or keys dynamically generate and change. This cipher data can show up as a false positive and showing differences in the compare. Ignore cipher data.

### Steps

1. Using Policy Automation, click the **Compare Exports** link from the left navigation menu. The **Compare Exports** screen displays.
2. Select a connection type: **Ping-Access, IDP, or SP**
3. From the **Environment** drop-down list box, select an environment.
4. From the **Select Applications** drop-down list box, select an application. Available exports for the selected application populate the **Select Export** list box.
5. Select an export from the **Select Export** drop-down list box.
6. Repeat steps 2 through 5 to setup the second part of the compare.
7. Click the **Compare**. The differences between two exports display (highlighted) in the third column of **Compare Results**.

### Audit Data

**Audit Data** is broken down into three parts: PingAccess Release Data, PingFederate Release Data, and Other Data. The **Release Data** sections display the records of every application policy or SAML connection that was created or promoted. The **Other Audit** data contains every other type of call to PingFederate and PingAccess.

**Note:** The **Other Audit** section is indispensable for troubleshooting application failures. Without checking log files, this UI can show the root cause of most Policy Automation failure.

- **Audit Data:** Click this menu item on left menu to display Audit Data screen. Click an application name for more details.
- **Release Data:** Click to view PingAccess or PingFederate log details for releasing packages to environments. Click an application name for more details.
- **Other Audit:** Provides all other log messages.
- **Search Filter:** Enter the search term to narrow down list of system messages. Example: enter **DEV** to show messages that include the string
- **Application Name hyperlink:** Click an **Application Name** link to inspect application data in a pop-up screen.

### Policy Testing

---

The PAMP Policy Test Tool (PTT) tests application policies in a given environment. The response is returned with any SSO Headers that might be configured for the policy. The Policy Test Tool enables agile policy development since policy logic can be vetted in advance of agent deployments. The Load Test suite provides administrators the insight to understand a performance impact of a given policy.

**Tip:** Proxy Based applications must be physically deployed to the network. The PingAccess engine does not allow proxy resources to be tested in the same manner as agent deployments.

### Architecture overview

The PTT has a built-in agent that leverages the PingAccess Agent Protocol. It is able to instantiate itself and act like any other agent on the network. For Proxy-based applications, the PTT sends requests over the proxy connection. Due to the difference in architecture, the protected application must be running and available behind the PingAccess Proxy.

The following diagram shows the differences between the Agent-based and Proxy-based testing:

The PTT has a built-in PingAccess Agent that talks to PingAccess Policy Server over PingAccess Agent Protocol (PAAP) to evaluate the Policies. PAAP is a simple HTTP based protocol for communication and interaction between PingAccess Policy Server and PingAccess agents. The Agent Configuration is downloaded and stored in a file, which is used by the built-in Agent to communicate with PingAccess for Policy evaluation.

A protected web application is required to test proxy resources. PTT communicates with PingAccess using HTTP protocol and evaluates the policies.

See [Agent Vs Proxy Testing](#) in the troubleshooting section for more information.

## Settings

Policy Test Tool (PTT) identifies how a user authenticates by selecting adapters or authentication context it needs to pass with the request to determine the adapter for user authentication. Customize authentication adapters for PTT from the **Policy Test Tool > Settings** screen.

- **Environment:** Choose an environment for the adapter configuration. Each environment is setup individually.
- **Adapter:** Configures the values that the PTT uses to auto-fill the authentication.
  - Allows the PTT to abstract the entire authentication process from the user and show the complete UI on a single screen and without redirections.
  - For the default authentication adapter, select an IdP Adapter Mapping created in PingFederate for user Authentication.
  - If the authentication context ACR is not defined, PingAccess Policy Tool uses the Default Authentication Adapter defined
- **Configuration:** Defines how the credentials pass.
  - HTML configuration is recommended since Basic Configuration is used where the user is challenged for credentials with basic pop-up
  - Uses the basic configuration setting if the authentication mechanism uses the authorization header.

### Create adapters

#### About this task

An Authentication Context (ACR), a Default Authentication Adapter, and a PingFederate Adapter are input from **Settings**.

#### Steps

1. Using the Policy Test Tool, click **Settings** from the left navigation menu.
2. Select an authentication context or adapter to open the section.

- **Authentication Context (ACR):** Authentication Context (ACR) settings determine the adapter that PingFederate will use for Authentication while evaluating a policy. If the ACR is not setup for an application, the default Authentication Adapter below is used.
  - **Default Authentication Adapter:** If a rule is not setup for the protected application in PingAccess, the policy is evaluated against the default Authentication adapter configured in this section. If a default adapter is not configured and a rule is not setup in PingAccess, authentication fails because an adapter is not configured for user authentication.
3. From the **Environment** drop-down list box, select an environment.  
The adapters for the selected environment load. Enter the adapter information for each environment that will be used by the adapter (For example, DEV and PROD)
  4. Select an adapter from the drop down list box.  
The configuration syntax for the ACR selected displays.
  5. Select a configuration to populate the configuration syntax button using PAPM.  
**Note:** HTML configuration is recommended for testing.
    - **Basic Configuration:** Sends the Authorization Header instead of a username and password in the request.
    - **HTML Configuration:** Sends username and password. The HTML configuration is recommended when the user is challenged for credentials with a basic pop-up.
  6. Click **Save Configuration**.

## Logic testing

Policy Test Tool does not support strong authentication. These adapters are pre-configured by PAPM but may require customizations by the user.

- Authentication Context (ACR)
- Default Authentication Adapter

PTT is capable of testing agent based and proxy based applications. See [Architecture overview](#) on page 433 to understand the difference between the two.

- **Select Test Configuration:** Select the environment, application, context, and test resource for the test. For site applications, the test resources should be a valid endpoint.
- **Evaluate Policy:** Use this section for testing policy logic using a single user. Provide the test user credentials. Check Groovy script option for Proxy based applications. See [Display headers for a proxy based application](#) on page 437 for more information. Click **Save** to evaluate the policy and display results.

## Processing steps

After a test executes, a summary of the test results display on the right side of the screen. Click **View Processing Steps** to see a breakdown of the steps the tool executed. This is helpful to diagnose a test that does not complete. The step that caused the error will display at the bottom of the step list.

## View test results

The **Test Results** tab contains an audit log of all Logic tests executed in the PTT. Load test do not display on this tab, they display on the [Load Test Results](#) tab.

- **HTML Return Content:** Click to view the HTML Return Content. The **Document View** can display download page content with a proxy format but not with the agent format. The **Raw Message** displays unformatted data returned.
- **User:** Displays the user ID that is sent to the application to execute the test.
- **Executor:** The user ID that logged into PAPM who configured and executed the test.

## Execute a PingAccess logic test

### About this task

For Proxy based applications, PingAccess acts as a gateway. Only the authorized requests reach the target web application server.

Agent based applications are intercepted at the target web application server by a PingAccess Agent. PingAccess Policy Server then makes the access decisions based on the policies configured.

Below are the steps to test Agent based or Proxy based policies using PTT.

### Steps

1. Click the **PingAccess Test** link in the PTT.
2. In the **Select Test Configuration** section, select an environment and click the **Load** button. The applications for the selected environment populate the **Application** drop-down list box.
3. Select an application from the list.

The list of resources associated with the selected application displays.

4. Select a resource.

**Note:** The **lock** icon indicates a protected context resource and the **unlock** icon indicates an unprotected context resource.

The selected resource populates the **Test Resource** field.

5. If needed, change the **Test Resource** field to contain URL of the application to be tested.
6. Optional step: To add SSO headers in the response, check **Add Groovy Script**.
7. Click **Save**.

Test results display on the right side of the screen.

- If the user is successfully authenticated and authorized, the resource is rendered and the SSO headers are returned if Add Groovy Script is checked.
- If the user is not authorized to access the resource, the test fails and generates a Forbidden error message.
- In case the test fails, headers are not returned and an error message displays on the screen.

## Execute a PingFederate logic test

### Steps

1. Click the **PingFederate Test** link in the PTT. The **PingFederate Policy Test** screen displays.
2. In the **Select IDP Configuration** section, select an environment and click the **Load** button. The applications for the selected environment populate the **IDP Connection** drop-down list box.
3. Select an **IDP Connection** from the list, click the load button. The **Connection URL** and **Adapters** for the selection populates.
4. Select a resource. The selected resource populates the **Test Resource** field.
5. In the **Evaluate Policy** section, enter a username and password.
6. Click **Save**.

Test results display on the right side of the screen. If successful, a green success banner will be displayed. Click on **SAMLResponse** to display decoded SAML Response.

## Display headers for a proxy based application

When accessing a proxy-based protected resource, the SSO headers are returned to the protected application by checking the **Add Groovy script** option. The SSO Headers are included in the response object of PingAccess and display in the PTT.

It all happens behind the scenes. When the **Add Groovy Script** option is selected, the PTT automatically creates a new rule (PATESTOOL\_SITEGROOVYSCRIPT) in PingAccess. This rule links to the protected application by creating a new policy for the protected resource. After the test is complete, the newly created policy deletes automatically. While the new rule still exists, it can be safely deleted.

## Load testing

The multi-threaded load test benchmarks PingAccess and PingFederate policy execution and response times. Metrics are stored in a local audit database and available via an interactive graphic console. User lists configure to automate the testing of both successful and unsuccessful policy logic to ensure that the wrong users are not given access.

### Load test calculations

The Thread Count, Requests per Thread, and AZ count are essentially load multipliers. Multiple all three values to get the total number of requests that will go to PingAccess or PingFederate.

Consider the following values for a Load Test with 5 different Test users (Threads) as an example:

Thread Count=5, Requests per thread=4, AZ Count=3.

In this configuration, 5 threads run 4 requests each (5\*4) which yields 20 login attempts. Each login attempt has 3 Authorizations so total Authorizations to be performed is 5\*4\*3=60.

### Load Test Policy

Input test configuration and load test policy.

## View load test results

Historical data found in the **Load Test Results** list can be used to compare the performance results before and after an upgrade and assist in troubleshooting. PTT saves a history of test results in a database that includes the response time and authorization time of the protected resource. The result file is stored as a CSV file at <PAPM\_HOME>/config/PolicyTestTool/download.

- Click the icon to view additional details of a load test.
- Click the **View Details** link to open the **Load Test Details** screen to view test results, charts, threads, and to download test results.

### Load Test Details: Results

- **90% Percentile Az Requests:** Displays the value where the 90% of requests are below that value and only 10% are higher. For example, only 10% of the total Authorization Requests (200 in this case) took more than 461ms.
- **90% Percentile Response Time:** Displays the value where 90% of the response times are below that value and only 10% are higher. For example, only 10% of the response times were higher than 3457ms.
- **Average Az Time:** Average authorization time.
- **Average Response Time:** Average response time of the requests.
- **Failed Az Requests:** Total number of failed authorization requests.
- **Failed Requests:** Total number of failed requests. This includes Authentication failures or failures caused due to network issues.
- **Max Az Time:** Maximum time taken for authorization. Time taken by all the Authorizations is recorded and the one with the highest value is identified which gives the Max Authorization Time, 1155 ms in this example.
- **Max Response Time:** Maximum response time taken by the request.

- **Successful Az Requests:** Total number of successful authorization requests.
- **Successful Requests:** Total number of successful requests.
- **Test Param : Application:** Name of the application being tested.
- **Test Param : Az Count:** Number of authorizations each thread will perform.
- **Test Param : EndTime:** Date and time when the load test was ended.
- **Test Param : Environment:** Environment for which the load test was performed.
- **Test Param : Executed By User:** Specifies the user who performed the load test. Displays in the Test Results list as Executor.
- **Test Param : Requests per Thread:** Specifies the number of requests each thread will make.
- **Test Param : Resource:** URL of the protected resource.
- **Test Param : StartTime:** Date and time when the load test was started.
- **Test Param : Status:** Status of the load test. For example, TERMINATED or COMPLETE. If the Load Test is TERMINATED, it specifies the username who terminated the test.
- **Test Param : Threads:** Total number of threads . In the above example, it is 20.

**Load test details: Charts**

**Load Test Details: Threads**

Displays information about the threads, number of users, used to execute the load test.

**Load Test Details: Save Data**

Click the **Save Data** link in the left navigation area on the **Load Test Details** screen to download a CSV file containing the Load Test Results for the selected test.

## Execute a PingAccess load test

### Steps

1. Follow the steps listed in [Execute a PingAccess logic test](#) on page 436
2. Click the **Load Test Policy** button.
3. Enter the Thread Count, Requests per thread and AZ Count as needed.
4. Add at least one user to the load test.
5. Click the **Load Test Policy**.  
The load test is executed. The status displays on the screen. If an error occurs, see [Managing error messages](#) on page 440 for more information.
6. Click **View Details**.
7. Click **Save Data** to save the results.  
The user is prompted to provide the location to save the results file in csv format.

## Execute a PingFederate load test

### About this task

### Steps

1. Follow the steps listed in [Execute a PingFederate logic test](#) on page 436 to configure the policy to test.
2. Click the **Load Test Policy** button.
3. Enter the Thread Count and Requests per thread.
4. Add at least one user to the load test.
5. Click the **Load Test Policy**.
6. Click **View Details**.
7. Click **Save Data** on the Result screen to save the results.

The user is prompted to provide the location to save the results file in csv format.

## Add multiple users to a load test

### About this task

An unlimited number of users can be added to a load test to simulate an event where multiple users attempt to access a policy at once. The users typed here are saved in a configuration file and will be available to use on every policy associated with the selected application. Each load test must have at least one test user.

**Note:** Use caution when loading test users because User Password information displays in plain text on the screen.

### Steps

1. Using the Policy Test Tool, from the **Load Test Policy** screen, click the **Configure Load Test Users** button.
2. Enter a user name and password separated by a comma and press the **Enter** For example, `testuser.1,password`. User IDs and passwords are case sensitive.  
A carriage return is added to the end the line and the cursor moves to the next line.
3. To add another user, repeat step 2. The following example shows the credentials of three users: Test User, Jane.Doe, and Be.Hill.
  - `TestUser,password`
  - `Doe,secretepw`

- Hill,87dsljh

4. Click **Save Users**.

5. Click the **Close (X)** icon to close the screen.

The **Test Policy** screen displays.

### Terminate a load test

#### About this task

Only one load test at a time is executed. To terminate a load test that is in process, follow the steps below.

#### Steps

1. Using the Policy Test Tool, click **Test Policy** from the left navigation menu.
2. Expand **Test Policy**.
3. Click **Result**.
4. Click the **Load Test Results** tab.
5. Select the test and click **Terminate**.

## Managing error messages

Error messages display in a light red box. Inside the message box, the Error Help Icon and HTML Return Content Icon contain additional information about the error.

## Policy Migration for CA SSO (Siteminder)

PAPM's PingAccess Policy Migration for CA SSO radically simplifies the migration process by automating policy transformations from CA Single Sign-On XPS policies to PingAccess and PingFederate. It creates working PingAccess policies from a SiteMinder policy export and integrates with the PingFederate and PingAccess APIs in a user-friendly manner. PAPM removes the guesswork from your policy migration and seamlessly transform CA SSO policies into to PingAccess.

### Migration overview

#### SiteMinder XPSExport

CA SSO (SiteMinder) XPSExport is a tool to export the SiteMinder policy data that is included with the SiteMinder install. XPSExport creates an XML file which may have dependency information based on the exported policy. That's why it is important how this information is used for the target environment. When moving SiteMinder policies from one environment to another, either as part of an upgrade or a policy migration, some objects that are environment-specific are included in the export file. Examples of these objects include:

- Trusted hosts
- HCO Policy Server settings
- Authentication scheme URLs
- Password services redirects
- Redirect responses

See [Migration process](#) on page 441 for more information.

#### Configuring templates

The CA SSO policy migration is heavily dependent on the configured policy templates. CA SSO does not have a concept of OIDC for web applications or a web session in the same way that PingAccess and PingFederate use these attributes. As such, it is not possible to directly import or map these attributes. However, it is possible to setup an application template that can capture the requirements of your applications.

## Remove imported XPS files

### About this task

The following steps describe how to remove imported XPS files that are no longer needed.

### Steps

1. Using Policy Migration for CA SSO, click **XPS Policy File** from the left navigation menu.
2. Click **Remove Imported Files**.
3. Click the **Delete** link for the file that you wish to delete.

## Migration process

The following steps describe the migration process. See the [Troubleshooting](#) on page 455 section for troubleshooting tips.

- [Configure the XPS export file](#) on page 441
- [Create PingAccess template objects](#) on page 442
- [Create PingFederate template objects](#) on page 442
- [Create PAM template group](#) on page 442
- [Upload the XPS export file](#) on page 443
- [Select the SiteMinder domain](#) on page 443
- [Map and import the policy domain](#) on page 444
- [Execute migration](#) on page 446
- [Validate migration](#) on page 446

## Configure the XPS export file

### About this task

A utility that is included with the SiteMinder install creates the XPS Export file.

### Steps

Type the following command on the SiteMinder server to create a full back-up with all objects:

```
XPSExport.exe <filename> -xb
```

- To export a specific domain:

```
XPSExport.exe <file name>-xo CA.SM::Domain@<xid>
```

- For example:

```
XPSExport.exe D:\temp\policydata_domain.xml -xo CA.SM::Domain@03-8754fa84-c8ee-47a5-ba9d-14bec505fb02
```

**Note:** If the object xid is unknown, either lookup in the full back or use `XPSExplorer => option 79` for domain, the `S` for search, then copy the xid to the above command

## Create PingAccess template objects

### About this task

The templates in this step are created in PingAccess and are used for the migration in [Create PAPM template group](#) on page 442.

**Tip:** Use Policy Automation to create a PingAccess application policy. PAPM will auto generate all of the policy objects required. After the objects are created, you can modify them manually to meet your specific requirements.

### Steps

1. Using PingAccess, create an agent object template per the policy requirements.
2. Using PingAccess, create a web session template object per the policy requirements.
3. Using PingAccess, create an identity mapping template per the policy requirements.
4. Using PingAccess, create a site object template per the policy requirements.

## Create PingFederate template objects

### About this task

Log into PingFederate to create OpenID Connect templates. These templates are referenced in [Create PAPM template group](#) on page 442.

### Steps

1. Using PingFederate, create an OpenID Connect template object per the policy requirements.
2. Using PingFederate, create an OpenID Connect client object per the policy requirements.

## Create PAPM template group

### About this task

Set up template policy objects for all of the policy components. These templated components are grouped into a Policy Group in PAM. This Policy Group is used to map the policy objects during the import phase.

**Tip:** Create a working application as a template to ensure that the LDAP lookups and objects are all able to work together.

There are two sections in the settings applet. The left pane creates new Policy group templates, and the right pane edits existing templates. The Policy Tool retrieves the template objects directly from your PingAccess and PingFederate admin servers.

### Steps

1. Open Policy Migration for CA SSO.  
The SiteMinder XPS Policy File upload screen displays.
2. Using PAM Policy Migration for CA SSO, click **Settings**.
3. From the **Environment** drop down list box, select the environment that contains the PingAccess and PingFederate templates for the migration create in [Create PingAccess template objects](#) on page 442 and [Create PingFederate template objects](#) on page 442.  
The template objects created for the environment load.
4. In the **Agent** box, select the agent object template for the migration created in [Create PingAccess template objects](#) on page 442.
5. In the **Web Session** box, select the web session object template for the migration created in [Create PingAccess template objects](#) on page 442.

6. In the **Identity Mapping** box, select the identity mapping template for the migration created in [Create PingAccess template objects](#) on page 442.
7. In the **Site** box, select the site object template for the migration created in [Create PingAccess template objects](#) on page 442.
8. In the **OIDC Policy** box, select the OpenID Connect policy template object for the migration created in [Create PingFederate template objects](#) on page 442.
9. In the **OIDC Client** box, select the OpenID Connect client template object for the migration created in [Create PingFederate template objects](#) on page 442.
10. Click **Create Policy Group**.

### Upload the XPS export file

#### About this task

#### Steps

1. Using Policy Migration for CA SSO, click **XPS Policy File** from the left navigation menu. The **XPS File Upload** screen displays.
2. Click **Choose File** and select the XPS export file created in [Configure the XPS export file](#) on page 441. The file name displays in the **Select SiteMinder Policy File** box.
3. Click **Process File**. You are notified once the import is complete. If something is wrong with the file, a message indicating an invalid input file displays.
4. Click **Begin Migration**.

**Note:** Processing times depend on the size of the SiteMinder domain configuration. If importing a small XPS file, then the policy migration can begin immediately. If importing an XPS file with over 500,000 lines, it may take up to two hours to process. Because this processing occurs in the background, the UI may incur a performance degradation until processing is complete.

### Select the SiteMinder domain

#### About this task

Choose a SiteMinder domain to import in this step.

#### Steps

1. Using Policy Migration for CA SSO, go to the **Migrate Policy** screen and choose the domain file for the application in **Select Domain File**.
2. Select a Ping environment in the **Ping Environment** list. The domains contained in the XPS export file displays.
3. Select the SiteMinder domain you want to migrate by clicking the radio button in the first column.
 

**Tip:** Navigate the list of domains by scrolling, using the page buttons below the list, or by searching for the domain you want to migrate. To search, click the Search dialog above the list to the right, and start typing. Searching is dynamic and your result set will narrow down as you enter more characters in the dialog.
4. Once you have selected the application domain you wish to migrate, click **Import Domain**. The domain is imported and the **Import Policy** screen displays

## Map and import the policy domain

### About this task

Once the export file has been uploaded and the policy domain is selected, map and import the policy domain on the Import Policy screen. The **Import Policy** UI provides the user with an interface to view the CA SSO policy objects and map them to a PingAccess and PingFederate application policy.

### Steps

1. Using Policy Migration for CA SSO, complete the **Ping Environment** section on the **Import Policy** screen.

Field	Description
Ping Environment	Selected Ping environment. This value is based on the selected Ping Environment in the Settings Screen.
Ping Import Type	SiteMinder Migration allows two types, Site or Agent. Basing on the selected type, artifacts will change.
Ping Application Name	Application name imported from SiteMinder configuration file. Administrators can modify the Name as per the requirement.
Authentication Requirement	Authentication requirements are policies that dictate how an Administrator must authenticate before access is granted to a protected web resource. Create authentication requirements lists to identify these authentication methods. PAPM displays a list of one or more authentication methods which can be used across multiple application resources or it can be overridden by selecting individual authentication requirement in the application resources section. The values entered here must match the result values defined for the Requested AuthN Context Selector configured within PingFederate, and are ordered from highest to lowest value.
Policy Group	Select a Policy Group (Application Template) that best matches the user directory (or directories) tied to the CA SSO policy.
Agent Configuration	Click to display the SiteMinder Domain related Agent Config Objects (ACO).

2. From the **Application Resources** section on the **Import Policy** screen, select the protected / unprotected SiteMinder realms to import into PingAccess.

Field	Description
<b>Select All</b>	<p>Selects all the application resources that will get created in PingAccess environment along with Application Creation.</p> <p><b>Tip:</b> If the SiteMinder Policy Domain that you are importing includes realms (URL resources) from multiple applications, use the <b>Select All</b></p>

	checkbox to deselect all realms. Then use the <b>Search</b> box to search for the realms that belong in the application definition. Use the <b>Select All</b> checkbox to re-select the filtered realms.
<b>Create</b>	Creates the necessary application resource artifacts in the PingAccess Environment.
<b>Resource Name</b>	The resource name will be created in the PingAccess Environment. Administrators can customize the name.  All text fields on this screen are editable.
<b>Resource Path</b>	Resources represent part of Web applications or APIs that have distinct security requirements. Resources specify what path prefixes and HTTP methods they apply to. Each application has at least the Root Resource which covers any requests not covered by other defined resources, and can have any number of additional resources. Resources may specify particular authentication requirements, including no authentication if the Anonymous checkbox is selected. Use this page to view and edit existing application resources and to define new resources.
<b>Rules</b>	Displays the rules if they are configured in SiteMinder Web Session Attributes. These Web Session attributes will be converted as Rules in PingAccess Application. Rules for access control and request processing.
<b>Search</b>	Search for a specific Application Resource. You can use search when there are multiple Application Resources and you want to search for a specific resource.
<b>ACO- Ignore Extensions</b>	Text box to enter any extensions to be ignored during the SiteMinder domain application migration. A resource is created called IgnoreExtensions that matches the values configured here.
<b>Bad URL Chars &amp; XSS Check</b>	Filter for characters or CSS that may form a valid, executable script when displayed by the browser. A rule is created that blocks these characters.
<b>Web Session Timeout</b>	Contains the maximum time out and idle time out in minutes. PAPM populates this value with the lowest value found in selected application resources (SiteMinder Realms).

3. Complete the **Application Virtual Host/Agents** section on the **Import Policy** screen.

Field	Description
Virtual Host	These are the virtual host names and ports from which PingAccess accepts requests (e.g.,

	myhost.com:80). A wildcard (*) is used to accept any host with the specified port (e.g., *:3000).
Site	These are site's target application Host and Port number.
Identity Mapping	These mappings show the HTTP response headers that will be generated to the protected application.  <b>Note:</b> If the Identity Mapping values do not match the values in the policy template or of the rules for the SiteMinder protected realms, then an error will be generated at import time. The policy will require some manual fixing to ensure that the attribute lookups match both the policy rules and the output HTTP headers.
Create Application	Create an application in the selected Ping Access Environment by using the pre-configured templates.

### Execute migration

#### Steps

1. Using Policy Migration for CA SSO, click **Create Application**.
2. The results display on the **Results** screen.
3. From the **Results** page, open any item to view the REST API request and response created.  
This is useful in troubleshooting when an operation reports an error.

#### Validate migration

To validate the migration, access the migrated application.

## Policy Migration for Oracle Access Manager

---

PAPM for Oracle Access Manager (OAM) optimizes the process of taking your existing Oracle Access Manager authentication and authorization policies, and migrating them to PingAccess and PingFederate. The tool simplifies the migration of OAM policies to PingAccess and PingFederate by exporting the policy domains from both versions to a common JSON format that PAPM can understand. This process helps remove the guesswork of how your application's authentication and authorization policies map to the PingAccess and PingFederate format.

**Note:** The migration tool supports OAM version 10g and 11gR2, and has been specifically tested with OAM versions: 10.1.4.3 and 11.1.2.3. OAM 11g R1 has a different policy structure and is not supported.

### Migration overview

Migrating OAM policies to Ping is a multi-step process. The setup of the tool and supporting components is a one-time activity, and the migration of policies is performed application by application via the user interface.

#### Migration Components

- **Export OAM Policy Store:** The OAM Policy Export Tool is a standalone Java program that can connect to either OAM 10g or 11g environments. Use the tool to export the OAM Policy Store to the PAPM JSON format. The JSON file is imported to the PAPM Migration Tool.

- **Load OAM Rule Processor Plugin:** The OAM Rule Processor Plugin for PingAccess adds support for the wildcard expressions used by OAM when defining URI resources for authorization. The OAM Policy Migration tool requires that this plugin be activated on all PingAccess servers before OAM policy migration takes place.
- **Configure Templates** is an important step in the Migration process as it directly reflects the PingAccess or PingFederate configurations which will be used by the migrated OAM policy. Administrators should verify the current OAM Domain requirements and replicate those configurations in PingAccess and PingFederate environments. Other settings that cannot be imported from OAM (because PingAccess and OAM work very differently) will be inherited directly from the template objects. The PAPM will use these configurations as a template to create the applications.
- **Import File and Select Domain:** After importing the JSON file from the OAM Policy Export Tool, an administrator will use the Select Domain Page to choose the application policy to be migrated. Selecting an OAM Domain and choosing to import will bring you to the Create Application Page.
- The **Select OAM Application** page shows the available Resources, associated Policies, and OAM Host Identifiers as they will be imported into the Ping Environment. This step will use the templates defined in Step 2 and create the applications in PingAccess and PingFederate environment.
- **Test:** After processing the Create Application Function, successfully created applications can be tested using Policy Test Tool to verify the migrated application policy.

### Configuring Environments

PAPM works with existing PingAccess and PingFederate environments from development to QA or production. OAM Migration requires at least one pre-configured PingAccess and PingFederate environment before setting up migration templates described below. See [Settings](#) on page 414 for details on how to configure connectivity to your PingAccess and PingFederate servers.

### Configuring Templates

Templates containing policy requirements are a critical component of the PingAccess Policy Migration for OAM tool. They contain PingAccess and PingFederate environment configurations for each type of application object.

As these objects are used during the application migration, you should check the current OAM domain configurations and create the equivalent artifacts in PingAccess as a template. The tool allows users to use templates multiple times for OAM Domains that share similar configurations.

### OAM Policy Export Tool

The OAM Policy Export Tool supports both OAM 10g (10.1.4.3) and 11gR2 (11.1.2.3) environments.

**Note:** The OAM Policy Domain Export Tool is a standalone tool independent of PAPM and is not accessed using the PAPM UI. The tool is located in the following location: <PAPM\_HOME>/extras/OAMExportUtility/

The tool exports the following into a JSON formatted file:

- OAM Host Identifiers
- Policy Domains
- Defined Resources
- Authorization Policies
- Policy Responses

The OAM servers must be operational for the export tool to work. Each version uses specific Policy API calls to extract policy store data before storing the data in the export file.

### Policy Domain Export Process

The OAM Policy Export Tool communicates with the **OAM 11gR2** environment via the REST Policy Administration API interface. To extract the **OAM 10g policies**, the tool uses a combination of LDAP and Native OAM API calls via the AccessServerSDK.

**OAM 11gR2** and **OAM 10g** follow a similar logical flow when exporting the data.

1. **Identify Application Domains:** Query the list of application domains
2. **Extract Data Cycles:** Iterate through each policy domain
  - a. Extract all the hosts from the Host Identifiers
  - b. Find all the defined resources
  - c. Determine which resources are protected and which have anonymous access
  - d. Extract all the authorization policies with allow and deny rules
  - e. Extract all of the policy responses
3. **Format and Normalize Data:** Transform the version specific format to a common JSON format.
4. **Create JSON File:** Write the JSON formatted data to an output file.

The resulting JSON file contains the source data used by the PingAccess Policy Migration for OAM tool.

### PAPM OAM Rule Plugin for PingAccess

PingAccess and OAM do not support the same resource definitions. To bridge this gap, the PAPM OAM Rule Plugin for Ping Access was developed. It can handle advanced resource and policy definitions that use multiple wildcards and/or regex expressions to define protected or unprotected resources.

This plugin is configured on PingAccess servers prior to starting the application migration process so that the correct rules and policies are configured when migrating each application to Ping.

If an OAM policy contains authorization expressions, it will probably contain rules that use the PAPM OAM Rule Plugin. This plugin will evaluate URI resources with OAM type resource wildcards and query strings that Ping does not support out of the box.

### Resource Matching Process

The PAPM Rule Processor follows the same logic for resource matching that Oracle Access Manager uses. This diagram shows the matching process for resources defined as a custom PingAccess rule using this plugin.

## Migration process

The following steps describe the migration process. See the [Policy Migration Tool for OAM](#) on page 458 section for troubleshooting tips.

- [Configure the OAM Policy Export Tool](#) on page 449
- [Export the OAM policy store](#) on page 450
- [Set up the OAM Rule Processor Plugin for PingAccess](#) on page 450
- [Create PingAccess template objects](#) on page 450
- [Create PingFederate template objects](#) on page 451
- [Create template object group](#) on page 451
- [OAM Policy Store file upload](#) on page 451
- [Select OAM application](#) on page 452
- [Configure import policy](#) on page 452
- [Execute migration](#) on page 454
- [Validate migration](#) on page 454

## Configure the OAM Policy Export Tool

### About this task

The OAM Policy Store export tool exports the entire policy store from OAM to a JSON formatted file. This file is then imported into the PingAccess Policy Migration tool for OAM, which is the next step of the process. The OAM Policy Export tool requires configuration to connect to an OAM environment to export the data. Please follow the steps below to configure the tool. For more information, see [OAM Policy Export Tool](#).

### Steps

1. Check that Java 1.8 is setup on the export utility server.

- Copy the export tool from the following location to any server that has connectivity to your OAM Servers. The export tool is located in the following location:

```
<PAPM_HOME>/extras/OAMExportUtility/
```

**Note:** For an **OAM 10g** export, AccessServerSDK is required. This is not required for OAM 11g exports. The SDK can be downloaded from Oracle at the following location: [https://docs.oracle.com/cd/E12530\\_01/oam.1014/e10355/as\\_api.htm](https://docs.oracle.com/cd/E12530_01/oam.1014/e10355/as_api.htm). An environment variable ACCESS\_SERVER\_SDK\_HOME must be set to the AccessServerSDK installation path.

- Update the OAM environment details in `application.properties` file that is located in the config folder for the OAMExportUtility (`<PAPM_HOME>/extras/OAMExportUtility/config/`).

**Note:** Passwords saved as plain text are encrypted by the utility during the export operation.

## Export the OAM policy store

### About this task

Ensure that your OAM Export Tool has been setup according to the instructions in the previous section of this document.

### Steps

- To execute the export utility, navigate to the directory where you have setup your OAM Export Tool.
- Run the export utility using `<PAPM_HOME>/extras/OAMExportUtility/bin/oamexport.sh` or `.bat`. Required parameters are as follows:

**OAM10g** - `oam10g [OAM10GADMINPASSWORD] [OAM10GLDAPPASSWORD]`

**OAM11G** - `oam11g [OAM11GPASSWORD]`

**Both** - `both [OAM10GADMINPASSWORD] [OAM10GLDAPPASSWORD] [OAM11GPASSWORD]`

**Note:** The exported data is stored in the `<PAPM_HOME>/extras/OAMExportUtility/output` folder as a JSON file, and will be named using the date and timestamp when the utility was executed.

**Note:** Java warnings should not be a cause for concern.

## Set up the OAM Rule Processor Plugin for PingAccess

### About this task

Enable the PAPM custom plugin on all PingAccess servers in the environment prior to the migration. This ensures the custom authorization rules can be correctly instantiated on the PingAccess servers.

### Steps

- To configure the plugin, copy `<PAPM_HOME>/extras/OAMPARulePlugin/papm-oam-pa-az-rule-VERSION.jar` to the **lib** folder of ALL your PingAccess servers.
- Restart each PingAccess server to enable the plugin.

## Create PingAccess template objects

### About this task

These templates are created in PingAccess and are used for the migration in Step 5.

### Steps

- Using PingAccess, create an agent object template using PingAccess per the policy requirements.
- Using PingAccess, create a web session template object using PingAccess per the policy requirements.

- Using PingAccess, create an Identity Mapping Template using PingAccess per the policy requirements.

**Note:** OAM supports multiple types of policy responses including HTTP Headers, HTTP Cookies, and HTTP Session variables. PingAccess will only support HTTP headers or JSON web tokens. You will need to make sure your applications support the PingAccess model for identity mapping during the migration process.

- Using PingAccess, create a site object template using PingAccess per the policy requirements.

### Create PingFederate template objects

#### About this task

Log into PingFederate to create OpenID Connect templates. These templates are used in the next step.

#### Steps

- Using PingFederate, create an OpenID Connect template object using PingAccess per the policy requirements.
- Using PingFederate, create an OpenID Connect client object using PingAccess per the policy requirements.

**Note:** Agents and Sites: PingAccess supports both Agent (Similar to an OAM Webgate) and Site (Reverse Proxy) based architectures. The Policy Group requires that you have a template for both types, and when you are in the process of migrating an OAM policy to Ping, you will have the ability to choose one or the other for applications as they are migrated.

### Create template object group

#### About this task

Configuring templates is critical to a successful migration of OAM Policy Domains. The objects created in the PingAccess and PingFederate environments must meet the application requirements for user authentication, user attribute lookups, and session variables such as timeouts, scope, and HTTP headers. A template group is created in the PAMP that groups these template objects for the migration. The tool retrieves template objects directly from PingAccess and PingFederate admin servers.

#### Steps

- Using the PAMP OAM Migration Tool, click **Settings**.
- From the **Environment** drop down list box, select the environment that contains the PingAccess and PingFederate templates for the migration.
- In the **Agent** box, select the agent object template for the migration.
- In the **Web Session** box, select the web session object template for the migration.
- In the **Identity Mapping** box, select the identity mapping template for the migration.
- In the **Site** box, select the site object template for the migration.
- In the **OIDC Policy** box, select the OpenID Connect policy template object.
- In the **OIDC Client** box, select the OpenID Connect client template object for the migration.
- Click **Create Policy Group**.

**Note:** The Create New Policy group is used to create new policy group templates. The Edit Policy group is used for editing existing templates.

### OAM Policy Store file upload

#### About this task

This step imports the JSON file created by executing the OAM Policy Export Tool in [Configure the OAM Policy Export Tool](#) on page 449.

## Steps

1. Using the PAPM OAM Migration Tool, click **JSON File Upload**.
2. Click **Choose File** and select the JSON export file. The export file was named using the date and time that the file was created.  
The file name displays in the **Select OAM Policy File** box.
3. Click **Process**.  
Once the import is complete, you will be notified. If something is wrong with the file, a message indicating an invalid input file displays.
4. Click **Begin Migration** to proceed to the next step.

## Select OAM application

### About this task

Select the OAM application to migrate in this step. This page displays by clicking the Begin Migration button from the **JSON Policy File Upload** screen.

## Steps

1. Using the PAPM OAM Migration Tool, from the **Select OAM application** screen, choose the domain file for the application in the **Select Domain File**
2. Select a Ping environment in the **Ping Environment** list.
3. Click **Display Domain**.  
The domains contained in the JSON export file display.
4. Select the OAM application domain that you wish to migrate by clicking the radio button in the first column. Navigate the list by scrolling, using the page buttons below the list, or by searching for the domain you want to migrate. To search, click the **Search** dialog above the list to the right, and start typing. Searching is dynamic and your result set will narrow down as you enter more characters in the dialog.
5. Once you have selected the application domain you wish to migrate, click the **Import Domain** button at the bottom of the screen.  
The domain is imported and the **Import Policy** screen displays.

## Configure import policy

### About this task

The **Import Policy** screen has several sections. Most of the data has been pre-populated from the OAM policy export. Choose the type of policy to create in the Ping environment, which template to use, and authentication requirements for the application resources. In addition, you can make modifications to the resources, environment details and identity mappings that are created in PingAccess.

## Steps

1. Using the PAPM OAM Migration Tool, configure the Ping environment in the **Ping Environment** list.

Ping Environment	This setting is static and was set when you choose the OAM Domain to import on the previous screen.
Ping Import Type	Select the type of PingAccess application, Site or Agent. Data in the bottom section will change based on which type you choose here.
Policy Group	The Policy Group selection is populated with the templates you created. These templates will determine the policies created when the

	application is migrated to PingAccess and PingFederate.
Ping Application Name	The name of the OAM Policy Domain is populated in this field. Edit the name if needed.
Authentication Requirement	Select how PingFederate will authenticate users for the application.

2. Configure application URIs in the **Application Resources** screen. Specify whether they are accessible without authentication, or have associated allow and/or deny policies,

Create Checkbox	The first column contains a checkbox that indicates whether the resource and associated policy will be created in the Ping environment. Most resources will be selected by default with the following exceptions since they are specific to an OAM environment: <ul style="list-style-type: none"> <li>• Any resource beginning with /access/oblix</li> <li>• Any resource beginning with /identity/oblix</li> </ul>
Name	Each resource and policy is assigned a name. The associated authentication scheme is also listed for informational purposes. The scheme is not imported to Ping.
Path	This field contains the URI that will be imported to Ping. Modify the URL as needed before the application is created in the Ping environment.
Anonymous	Anonymous checkbox is available for those resources that have an anonymous authentication scheme assigned in your OAM policy domain.
Rules	The rules displayed in this section are based on configurations in the OAM policy domain. If specific users or groups (or LDAP filter rules) are assigned to allow or deny authorization rules in OAM, the corresponding rule will be imported to Ping.

3. Configure Virtual hosts, Sites/Agents, & Identity Mappings. The information in this section is populated by the OAM host identifiers and OAM policy responses.

Virtual Host	Contains the hostnames and port numbers that end users will use in URLs to access the application in PingAccess. The list is pre-populated with the complete list from the OAM Host Identifiers in the OAM Policy Domain.
Site / Agent	The middle portion of this section will change from site to agent based on the import type chosen in the Ping Environment section at the top of the screen. The values populated are pulled from the site and agent templates defined on your settings screen described in Step 1. <ul style="list-style-type: none"> <li>• <b>Site:</b>– When the application is set as a site, then the application is protected using the PingAccess server as a reverse proxy, the</li> </ul>

host:port combinations listed here are the HTTP servers that the PingAccess server forward authenticated requests.

- **Agent:** - When the application is set as an agent, the application HTTP server is configured with a PingAccess Agent. The value listed here is pulled from the Agent Template and contains the host:port of the Agent listener on the PingAccess Server.
- **Identity Mapping:** Contains headers that are generated by PingAccess and injected into the HTTP response. The values listed here come from the OAM Policy Responses.

**Note:** OAM supports both HTTP Headers and HTTP Cookies while PingAccess supports HTTP Headers and Signed JWT Tokens. The migration tool supports the migration of HTTP Headers. It is possible that you will need to change this list to match your requirements, and developers of the application will have to change the application to support variables that PingAccess will support.

Ensure that your LDAP attributes that are listed here are valid in your LDAP identity store which is used by PingFederate. If PingFederate cannot match the attribute the migration will contain an error on the next step.

PingFederate is case sensitive when comparing attributes listed in this section to the LDAP Schema in the LDAP identity store. For example, if your list has an ldap attribute represented as 'givenname' but your LDAP schema has 'giveName', then your migration will have an error.

## Execute migration

### Steps

1. Using the PAPM OAM Migration Tool, review the settings and click the **Create Application** button at the bottom of the page to start the migration.

The PAPM OAM Migration Tool will create all the supporting objects within PingFederate and PingAccess.

Migration results display on the results page.

2. From the **Results** page, open any item to view the REST API request and response created. This is useful in troubleshooting when an operation reports an error.

### Validate migration

To test the migrated policy, access the migrated application.

## Disaster recovery

---

High availability is the measurement of a system's ability to remain accessible in the event of a policy tool failure. By design, PAM can only run on a single server. In the event of system failure, it is possible to copy the PAM `config` folder to another server and bring up the PAM.

The purpose of this section is to describe the configuration of the PAM for high availability and disaster recovery by providing an understanding of the following:

- **Communication:** The PAM communicates with PingAccess and PingFederate using standard APIs.
- **Data storage:** The PAM stores the data in the `PAM_HOME/data` directory and settings are stored in various properties files in the `config` file.

- **Back up process:** PAPM data is archived daily at approximately midnight server time to the following directory: `<PAPM_HOME>/data/backup`

### What to Save

All files that need to be saved are located under the `<PAPM_HOME>/config` and `<PAPM_HOME>/data` directories.

**Note:** PAPM is typically recoverable if these directories are backed up.

**Important:** PAPM only retains administrative configuration prior to that configuration being pushed to PingAccess and PingFederate operational environments. As it is not required for runtime, the risk of PAPM being unavailable is restricted to loss of access to the configuration retained in PAPM. It does not affect either PingAccess or PingFederate operational availability or performance when unavailable.

## Set up disaster recovery (data backup)

### About this task

The following example provides steps that can be followed as a simple mechanism to provide an example of automated backup.

### Steps

1. Setup a cronjob to archive the `<PAPM_HOME>/config` and `<PAPM_HOME>/data` folders daily or weekly.
2. Install the PAMM on a server.
3. SCP/FTP the `<PAPM_HOME>/config` and `<PAPM_HOME>/data` folders to the directory `product path` in the target server.
4. Unzip/UnTAR the archive file.
5. Start PAMM by going to `<PAPM_HOME>/bin` and invoke `run.bat/run.sh`.
6. Test PAMM console access via your browser and verify the configurations.

## Troubleshooting

---

All of the tools in PAMM provide online troubleshooting functions. This section details the best ways to troubleshoot errors with each of the tools.

- [PAPM logging](#) on page 455
- [Login issues](#) on page 456
- [Policy Migration Tool for CA SSO](#) on page 458
- [Policy Migration Tool for OAM](#) on page 458

### PAPM logging

The PAMM logger creates a series of organized log files for application troubleshooting.

Log Name	Description
<code>application.log</code>	<p>The <code>application.log</code> file contains all of the standard Java log output from PAMM.</p> <p>Log Format: <code>DATE-TIME-LOG_LEVEL-CLASS:-LOG MESSAGE</code></p>

`application-api.log`

The `application-API.log` file contains the auditable requests to PAPM.

Log Format: DATE TIME | COMPONENT | ADMIN USER | API REQUEST URL | TARGET IP | METHOD (GET, POST) | RESPONSE CODE | RESPONSE TIME

Delimiter: Pipe

## Login issues

### Before you begin

If the LDAP account is misconfigured and access to the PAPM is locked out, you can manually reset the login back to the OOTB file-based login module.

### Steps

1. Using Terminal, edit the properties file located at `PAPM_HOME/config/application.properties`.

Set: `papm.force-database-authentication=true`

2. Restart PAPM.

## Policy Automation

Policy Automation contains two sets of audit records:

- Successful releases (affecting live data and functions)
- Other audit records: Other API calls and **failed API transactions**

The **Other Audit** section is invaluable for troubleshooting errors in the Policy Promotion Tool.

1. **Using Policy Automation Tool > Audit Data** click **Other Audit** to open the Audit Data screen.

**Tip:** It may be useful to search for FAILURE messages on this tab.

2. Click the link with the application name, for instance, XXXTEMPLATEAGENTXXX.

This link displays the RESTful API request and response output. The output below contains a failed result.

## Result

```

{
  "msg": "Application create failed. ( Application : XXXTEMPLATEAGENTXXX & Environment : dev )",
  "result": "ERROR",
  "requesturl": "https://pingad.cyberinc.com:49999/PolicyTool/api/PolicyPromotion/appmanagement/dev/XXXTEMPLATEAGEN
TXXX?applicationtype=Agent&vhostlist=XXXTEMPLATEAGENTXXX:1111&siteTargetList=&cache=true&cleanUpOnError=true&fromte
mplate=true",
  "retCode": 0,
  "response": [
    {
      "jsonOutput": "{\"id\":3,\"host\": \"xxxtemplateagentxxx\", \"port\":1111, \"agentResourceCacheTTL\":0, \"keyPair
Id\":0}\n",
      "jsonInput": "{\"host\": \"XXXTEMPLATEAGENTXXX\", \"port\": \"1111\"}",
      "operation": "virtualhosts",
      "result": "SUCCESS"
    },
    {
      "jsonOutput": "{\"resultId\": \"openid_connect_role_not_enabled\", \"message\": \"This resource is not available
because PingFederate does not have the OpenID Connect role enabled.\\n\"",
      "jsonInput": "{\"id\": \"XXXTEMPLATEAGENTXXX\", \"name\": \"XXXTEMPLATEAGENTXXX\", \"accessTokenManagerRef\": {\"id
\": \"PAToken\", \"location\": \"https://pingad.cyberinc.com:9999/pf-admin-api/v1/oauth/accessTokenManagers/PAToken
\", \"idTokenLifetime\": \"5\", \"includeSriInIdToken\": \"false\", \"includeUserInfoInIdToken\": \"true\", \"attributeCo
ntract\": {\"coreAttributes\": [{\"name\": \"sub\"}], \"extendedAttributes\": [], \"attributeMapping\": {\"attributeSourc
es\": [], \"attributeContractFulfillment\": {\"sub\": {\"source\": {\"type\": \"TEXT\", \"value\": \"Changeme\"}}, \"issuan
ceCriteria\": {\"conditionalCriteria\": []}}}}",
      "operation": "oauth/openIdConnect/policies",
      "result": "ERROR"
    }
  ]
}

```

In this example, the OpenID connect role was not enabled on this server:

Server Settings

System Administration	System Info	Runtime Notifications	Runtime Reporting	Account Management	Roles & Protocols	Federation Info	System Options	Metadata Signing
Metadata Lifetime	Summary							

Select the role(s) and protocol(s) that you intend to use with your federation partners.

ENABLE OAUTH 2.0 AUTHORIZATION SERVER (AS) ROLE

OPENID CONNECT

This method helps troubleshoot many types of API errors, such as missing data, orphaned-linked records that cannot be deleted, incompatible data (across Ping API versions), etc.

## Policy Test Tool

The Policy Test Tool provides an interface to:

- Test policy function
- Provide performance metrics
- Enable load testing of policy logic

Since the PTT is a testing tool, expect error conditions. It is important to recognize where the Policy Test Tool will show a success and when it will encounter issues. For example, strong authentication is not supported; resources with policy requirements for strong authentication will always fail.

**Note:** Strong authentication is not supported.

### Ports, Connectivity

Unlike the other utilities that require API access, the Policy Test Tool additionally requires direct access to the proxy, login, and agent ports for the PingAccess and PingFederate servers for each environment. These ports are typically:

- PingFederate Engine: 9031
- PingAccess Proxy: 3000
- PingAccess Agent: 3030

### Agent vs. Proxy Testing

The Policy Test Tool contains an embedded PingAccess Agent. This enables testing without ever deploying the application to the network. Any protected resource can be tested for authorization, response times, and mapped identity headers.

### Agent Testing

Note the 'Agent' indicator in green. Any test resource should work, even resources with an '\*' instead of a true URL endpoint.

### Proxy Testing

Unlike the Agent, a Proxy-Based test resource **MUST** go to a real resource on the network and a true application page. It is not possible to virtually test proxy resources in the same way as an agent model due to the PingAccess system design.

The resource must be a true application endpoint or it will result in an error.

## Policy Migration Tool for CA SSO

The Policy Migration Tool for CA SSO has a couple of features to troubleshoot policies online. However, it is important to ensure that the process begins with complete data.

### Incomplete XPS export

The SiteMinder XPS Export should use the `-b` backup option to capture all data. If a partial policy backup is taken, some data may be missing. More importantly, the export data may be missing the Agent Configuration Object (ACO). This will effectively disable any policy import of unprotected resource extensions (`ignoreExtensions`) and the cross site scripting characters.

### Poor performance:

If importing a large XPS Export file (>20MB), wait one to two hours before continuing to choose a domain. A time consuming background database process needs to parse hundreds of thousands of lines of XML and transform the data into a JSON based format. Once the process is complete, the tool should be very responsive.

### Incorrect user store:

The migration process builds HTTP header and authorization lookups from a template policy. However, if the template policy does not link to the correct user directory or database, the migration process will build a stubbed OIDC policy (as it cannot find the appropriate data to map). Ensure that the template links to the same user store as the imported policy.

### Missing HTTP response headers:

As mentioned above, the import process uses a template. If the template does not include the appropriate lookups (even to the correct user store) a valid mapping cannot occur. This will also result in stubbed attributes in the OIDC policy as well as attributes PingAccess identity mapping object that cannot be filled.

**Note:** Once a migration has completed, the results screen displays a list of the created objects. Each of these objects can be click to inspect the data objects used to create the policies. If you navigate away from the results screen, then simply go to the **Audit Data** menu under the SiteMinder Migration Tool.

## Policy Migration Tool for OAM

Below are some common issues that may be encountered when using the PingAccess Policy Migration tool for OAM.

### Domain import failure

When an OAM application domain is imported into PingAccess, the import is not one operation, but many calls to the Ping REST APIs. If any of these API calls report an error, then the OAM domain migration will report a failure.

**Site errors**

When migrating an OAM application domain to a site (reverse proxy) based application in PingAccess, the list of hostnames in the site section of the migration tool is populated from the OAM host identifiers. This represents the application HTTP servers that the authenticated and authorized requests are forwarded to by the PingAccess proxy server.

This presents the same issue as described for virtual host errors above. When the PingAccess Policy Migration tool for OAM pushes the list of hosts to the site target in PingAccess, every DNS hostname is resolved to ensure it is a valid hostname. If an invalid hostname is detected, then the operation will fail, and the site targets will need to be created manually.
